Obviously, our ordering process depends on Λ. If $\Lambda = \{0, 0.1, 0.2, 1\}$, then $S_\Lambda(\mathcal{A}_1) = 0.68$ and $S_\Lambda(\mathcal{A}_2) = 0.592435$, so $\mathcal{A}_2 \prec_\Lambda \mathcal{A}_1$. If $n \in \mathbb{N}$ and $\Lambda_n = \{0, 1/n, 2/n, \ldots, (n-1)/n, 1\}$, then:

$$S_{\Lambda_n}(\mathcal{A}_1) = \frac{2(n-1)}{n}, \quad S_{\Lambda_n}(\mathcal{A}_2) = \frac{3}{n^2} \sum_{k=1}^{n-1} \left[k \left(\sqrt{n^2 - k^2} - \sqrt{n^2 - (k+1)^2} \right) \right],$$

so $\mathcal{A}_1 \prec_{\Lambda_n} \mathcal{A}_2$ for all $n \in \mathbb{N}$, $n \geq 2$.

In [1], Abbasbandy and Asady proposed a modification of the distance based approach (called the *sign distance* that depends on a real number $p \geq 1$) in order to overcome the shortcomings of previous techniques for ranking FNs. In their work, they did a complete comparison between their methodology and previous processes (Yager [18], Chen [4], Chu and Tsao [6], Yao and Wu [21] among others) using five subsets of triangular or trapezoidal FNs. Next, we use some of these subsets so as to compare their methodology with our technique.

The FNs $\mathcal{A} = (0.3/0.5/0.7)$, $\mathcal{B} = (0.3/0.5/0.8/0.9)$ and $\mathcal{C} = (0.3/0.5/0.9)$ were considered in [1] (Example 1, Set 3) and in [13] (Example 5, Set 3), producing the results showed in Table 1.

FNs	Yager	Chen	Chu-Tsao	Yao-Wu	Abbas.-Asady $p=1$	Abbas.-Asady $p=2$	Nejad-Mashinchi	Method with Λ_4
$\mathcal{A}$	0.5	0.375	0.25	0.5	1	0.7257	0.0714	0.15
$\mathcal{B}$	0.55	0.425	0.31526	0.625	1.25	0.9416	0.1387	0.4125
$\mathcal{C}$	0.625	0.55	0.27475	0.55	1.1	0.8165	0.1044	0.225
Result	$\mathcal{A} \prec \mathcal{B} \prec \mathcal{C}$	$\mathcal{A} \prec \mathcal{B} \prec \mathcal{C}$	$\mathcal{A} \prec \mathcal{C} \prec \mathcal{B}$	$\mathcal{A} \prec \mathcal{C} \prec \mathcal{B}$	$\mathcal{A} \prec \mathcal{C} \prec \mathcal{B}$	$\mathcal{A} \prec \mathcal{C} \prec \mathcal{B}$	$\mathcal{A} \prec \mathcal{C} \prec \mathcal{B}$	$\mathcal{A} \prec \mathcal{C} \prec \mathcal{B}$

Table 1: Comparison between fuzzy rankings, where $\mathcal{A} = (0.3/0.5/0.7)$, $\mathcal{B} = (0.3/0.5/0.8/0.9)$ and $\mathcal{C} = (0.3/0.5/0.9)$.

We emphasize that our results are reasonable and they do not coincide with other previous techniques.

Notice that ranking methods that verify the property in the fourth bullet could also be interpreted as a measure of the imprecision associated to a FN rather than an evaluation of its location. Thus, when there is no imprecision, this order does not permit us to distinguish between crisp FNs. In this sense, we point out that this method is in agreement with fuzzy set inclusion, but not with the ordering of real numbers. Comparing with the previous fuzzy rankings, this property could yield to a different ordering, as in the following example.

The FNs $\mathcal{A} = (0/0.4/0.7/0.8)$, $\mathcal{B} = (0.2/0.5/0.9)$ and $\mathcal{C} = (0.1/0.6/0.8)$ were also considered in [1] (Example 1, Set 4) and in [13] (Example 5, Set 4), producing the results showed in Table 2.

Abstract

In this work, we consider a generalized fourth order nonlinear wave equation from the point of view of the theory of symmetry reductions in partial differential equations.

Key words: Symmetry reductions, partial differential equations

1 Introduction

The description of physical, biological and other process is frequently given by nonlinear partial differential equations (PDEs) and their solutions play an important role in the understanding of these process. A large number of publications has been done in this area and many methods have been derived for finding analytical solutions for integrable nonlinear PDEs. Recently the nonlinear wave equation

$$u_t + \alpha u^n u_x - \delta(u^m u_x)_x + u_{xx} + \sigma u_{xxx} + u_{xxxx} = 0 \tag{1}$$

has been considered in [5], where the author has derived exact solutions for equation (1) by using Painlevé property. The machinery of Lie group theory provides the systematic method to search for special group-invariant solutions. For PDEs with two independent variables, as is equation (2), a single group reduction transforms the PDE into ODEs, which are generally easier to solve than the original PDE. Most of the required theory and description of the method can be found in [6, 1, 2] and many recent papers using this method have been published in [3, 7, 4].

 ISBN: 978-84-617-8694-7

The aim of this work is to consider the following generalization of Eq. (1)

$$u_t + u_{xx} + cu_{xxx} + u_{xxxx} + f(u)u_x - g'(u)u_x^2 - g(u)u_{xx} = 0. \tag{2}$$

We apply Lie classical method to equation (2) in order to obtain exact solution, as well as, to derive conservation laws for these equations by using the multipliers method. We also will apply the multiplier method to the reduced ODEs in order to reduce the order directly.

2 Classical symmetries and reductions

Lie classical method is based on the determination of the symmetry group of a differential equation, i.e., the largest group of transformations acting on dependent and independent variables of the equation so that maps solutions of the equation into other solutions.
In order to apply Lie classical method to equation (2) we consider the one-parameter Lie group of infinitesimal transformations in (x, t, u), where ϵ is the group parameter. The symmetry group of equation (2) will be given by the set of vector fields of the form

$$\mathbf{v} = \xi(x,t,u)\partial_x + \tau(x,t,u)\partial_t + \eta(x,t,u)\partial_u. \tag{3}$$

Equation (2) admits a Lie point symmetry provided that

$$pr^{(4)}\mathbf{v}(\Delta) = 0 \qquad \text{when} \qquad \Delta = 0,$$

where $\Delta = u_t + u_{xx} + cu_{xxx} + u_{xxxx} + f(u)u_x + g'(u)u_x^2 - g(u)u_{xx}$ and $pr^{(4)}\mathbf{v}$ is the fourth prolongation of the vector field (3), we obtain a set of determining equations for the infinitesimals $\xi(x,t,u)$, $\tau(x,t,u)$ and $\eta(x,t,u)$. By solving the determining system we obtain the following results:

Case 1. The point symmetries admitted by equation 2 in the general case are generated by

$$\mathbf{v_1} = \partial_x, \qquad \mathbf{v_2} = \partial_t. \tag{4}$$

Case 2. For $f(u) = -\dfrac{\ln(f_1+u)}{f_0} + f_2$ and $g(u) = g_0$, with f_0, f_1, f_2 and g_0 arbitrary constants, besides $\mathbf{v_1}$ and $\mathbf{v_2}$ we obtain a new generator:

$$\mathbf{v_3} = t\partial_x - f_0(f_1+u)\partial_u. \tag{5}$$

Case 3. For $f(u) = f_0 + f_1(-g_1+u)^{\frac{3g_0}{2}}$, $g(u) = (g_1-u)^{g_0}g_2 + 1$ and $c = 0$, with f_0, f_1, f_2, g_0, g_1 and g_2 arbitrary constants, besides $\mathbf{v_1}$ and $\mathbf{v_2}$ we obtain a new generator:

$$\mathbf{v_4} = \left(t + \frac{x}{3f_0}\right)\partial_x + \frac{4t}{3f_0}\partial_t + \frac{2(g_1-u)}{f_0\, g_0}\partial_u. \tag{6}$$

 ISBN: 978-84-617-8694-7

Case 4. For $f(u) = f_0 u + f_1$, $g(u) = g_0$ and $c = 0$, with f_0, f_1, and g_0 arbitrary constants, besides $\mathbf{v_1}$ and $\mathbf{v_2}$ we obtain a new generator:

$$\mathbf{v_5} = t\partial_x + \frac{1}{f_0}\partial_u. \tag{7}$$

The corresponding generators of the optimal system of subalgebras for each case respectively are:

$$\langle \lambda\mathbf{v}_1 + \mathbf{v}_2\rangle,\ \langle \lambda\mathbf{v}_1 + \mathbf{v}_2,\quad \beta\mathbf{v}_2 + \mathbf{v}_3\rangle,\ \langle \lambda\mathbf{v}_1 + \mathbf{v}_2,\quad \mathbf{v}_4\rangle,\ \langle \lambda\mathbf{v}_1 + \mathbf{v}_2,\quad \beta\mathbf{v}_2 + \mathbf{v}_5\rangle$$

where $\lambda, \beta \in \mathbb{R}$ are arbitrary. In the following, reductions of Eq. (2) to ODE's are obtained using the generators of the optimal system.

Reduction 1: For case 1 and by using the generator $\lambda\mathbf{v}_1 + \mathbf{v}_2$ we obtain the similarity variable and similarity solution

$$z = x - \lambda t, \quad u = h(z) \tag{8}$$

and the ODE_1

$$h_{z\,z\,z\,z} + c\,h_{z\,z\,z} - g\,h_{z\,z} + h_{z\,z} - g_h\,(h_z)^2 + f\,h_z - \lambda\,h_z = 0. \tag{9}$$

Reduction 2: For case 2, by using the generator $\beta\mathbf{v}_2 + \mathbf{v}_3$ and setting $f_0 = 1$, $f_1 = f_2 = 0$, we obtain the similarity variable and similarity solution

$$z = \beta x - \tfrac{t^2}{2}, \quad u = h(z)e^{\frac{-t}{\beta}} \tag{10}$$

and the ODE_2

$$-\beta^5\,h_{z\,z\,z\,z} - \beta^4\,c\,h_{z\,z\,z} + \left(\beta^3\,g_0 - \beta^3\right)\,h_{z\,z} + \beta^2\,\log(h)\,h_z + h = 0. \tag{11}$$

Reduction 3: For case 3, by using the generator $\mathbf{v}_4$ and setting $f_0 = g_0 = 1$, $g_1 = 0$, we obtain the similarity variable and similarity solution

$$z = xt^{\frac{-1}{4}} - t^{\frac{3}{4}}, \quad u = \frac{h(z)}{\sqrt{t}} \tag{12}$$

and the ODE_3

$$-4\,h_{zzzz} - 4\,g_2\,h\,h_{zz} - 4\,g_2\,h_z^2 + z\,h_z - 4\,f_1\,h^{\frac{3}{2}}\,h_z + 2\,h = 0. \tag{13}$$

Reduction 4: For case 4 and by using the generator $\beta\mathbf{v}_2 + \mathbf{v}_5$, we obtain the similarity variable and similarity solution

$$z = \beta x - \frac{t^2}{2}, \quad u = \frac{t}{\beta f_0} - h(z) \tag{14}$$

and the ODE_4

$$-\beta^4\,h_{z\,z\,z\,z} + \beta^2\,g_0\,h_{z\,z} - \beta^2\,h_{z\,z} + \beta\,f_0\,h\,h_z - \beta\,f_1\,h_z + \frac{1}{\beta\,f_0} = 0. \tag{15}$$

 ISBN: 978-84-617-8694-7

3 Conclusions

In this work, we have obtained Lie symmetries of the fourth order nonlinear wave equation (2). We have derived the optimal system of one-dimensional subalgebras of the invariant equation and we have obtained reductions to ODE's. All the low order conservation laws will be achived by using the multiplier method. Moreover, we will search for exact solutions.

Abstract

Particle Swarm Optimization (PSO) algorithms have been shown to be highly efficient in finding patterns which appear repeatedly in a temporal series. A key component in these algorithms is the notion of distance used to compare sequences inside the series. In this paper we study the behavior of a variant of the usual PSO algorithm, where stronger interaction between the agents of the swarm is taken into account, when we use some naive distances.

Key words: Time Series, Pattern Recognition, Particle Swarm Optimization.
MSC 2000: 62-04, 62M10

1 Introduction

Time series appear naturally in any situation where data can be collected. The analysis has been long used in economy, biology, physics, medicine, industry, sociology, etc. as a mean to understand all sort of phenomena from measurements taken at different times. A particularly important application of this analysis consists in making predictions about the evolution of the object of study. A key tool to do so, relays in the identification of patterns that repeat themselves through the series, which is, in itself, a relevant structural information about the data [10, 11]. By interpreting as a time series any sequence, despite being obtained in a different context, such as imaging, we can apply tools developed for time series analysis to an even broader scope [8].

 ISBN: 978-84-617-8694-7

In the literature we may find many different approaches to this subject. Typically, the proposed algorithms are restricted to the comparison of same-length intervals in the series, albeit we can find some references where this restriction does not apply [15, 17, 18, 20]. In the last decade, algorithms based on what is known as Particle Swarm Optimization (PSO) [2, 3] have become popular due to their high performance and applicability to very different contexts [15, 11, 5, 13].

The idea behind the particle swarm optimization algorithms is to compare *simultaneously* different pairs of subsequences within the time series, chosen randomly. These pairs are considered to be the position of an agent in the swarm. A measure of how good a given position -in the ambient space of our agents- is given. Then each agent checks how good its current position is and moves to a new one, taking into account the best positions found, by itself and all any of the other individuals in the swarm, to choose which direction it should follow.

The goal of this paper is, in the one hand, to review the structure of PSO algorithms and how it can be interpreted in the context of pattern recognition, as well as summarizing some recent related works. In the other hand, we want to stress the importance of choosing an adequate notion of distance to compare subsequences of the time series.

Section 2 is dedicated to the formulation of the problem. We will also briefly review the common structure of PSO algorithms in this context, as well as discussing some of the considerations that should be taken into account. Next, in section 3 we propose some modification to the usual algorithm based on general swarming algorithms [9, 12, 4], in order to accelerate the convergence, and study different options to compare pairs of subsequences in the temporal series. This paper is intended as a preliminary work to establish the starting ground upon which we can build; hence we will limit ourselves to consider a few naive notions of distance, to exemplify how much, even in this cases, the performance of the PSO algorithm is dependent on what it means to be close for two subsequences of series. We present the results of our simulations and compare the performance achieved with each distance in Section 4.

2 A particle swarm optimization algorithms for pattern recognition

As we said in the introduction the basic idea of a PSO algorithm is to generate a swarm of agents that move in an appropriate space so that each of them can evaluate the adequacy of the position it occupies according to a fitness measure and explore its surroundings to find the position where the optimal is achieved. To do so, it is useful to let the agents remember

 ISBN: 978-84-617-8694-7

the position that yielded the best outcome of this measure. With this idea in mind, an agent can be thought of as a data structure $\mathsf{a}_i=\{\mathsf{x}_i, \mathsf{v}_i, \mathsf{cv}_i, \mathsf{bv}_i, \mathsf{bvx}_i\}$, where x_i represents the current position of the agent, v_i the velocity with which it is moving, i. e. the rule according to which it will choose a new position to explore, cv_i the value of the fitness measure in its current position, bv_i the best value it has found and bx_i is the position corresponding to that best value. We should also think of the swarm as an entity of itself, consisting of the collection of all agents, to which we will associate the best value and position encountered by any agent, gbv and gbx.

Using this framework, all PSO algorithms share a common core consisting in a double loop such as the one described by Algorithm 1, where, following with the analogy with the laws of movement, we shall call *acceleration* to the rate of variation of the velocity of the agents.

Algorithm 1 Core of the PSO algorithm.

```
1: while "optimal is improving" do
2:     for ALL agents IN swarm do
3:         dv_i ← Acceleration(agent, Swarm)
4:     end for
5:     for ALL agents IN swarm do
6:         x_i ← ← x_i) + dt· v_i
7:         v_i ← v_i + dt· dv_i
8:         cv_i ← OptMeasure(x_i)
9:         if cv_i < bv_i then
10:            bv_i ← cv_i
11:            bx_i ← x_i
12:            if gbv > bv_i then
13:                gbv ← bv_i
14:                gbx ← bx_i
15:            end if
16:        end if
17:    end for
18: end while
```

In order to use it for our purpose, we need an appropriate notion of position and velocity. Since our aim is to compare subsequences of a time series, it is natural to identify the position of an agent with these subsequences. Following the ideas in [15] we will define the position to be a 4-tuple, $\mathsf{x}_i=[\mathsf{x}_i^0,\mathsf{l}_i^0,\mathsf{x}_i^1,\mathsf{l}_i^1]$, where the first and third elements denote the start of the subsequences to compare and the second and fourth, their respective lengths.

 ISBN: 978-84-617-8694-7

An easy way to codify this, is to identify x_i^0 and x_i^1 with indices within the series and, if we assume that the time series is evenly distributed, l_i^0 and l_i^1 with the number of indices that constitute each subsequence. Thus, we can think of an agent moving in a subset $\mathbb{N}^4$. This approach implies strict restrictions in some (potentially all) of steps 3, 4 and 5 of the PSO algorithm. Namely, since x must be an unsigned integer, some adjustments are in order: we may force dt and v, and hence dv, to also be integers or we can correct the final value of x at each step to meet the requirements. Additional checks are necessary to ensure that the indices remain within meaningful boundaries: x_i^0 and x_i^1 must be smaller than the size of the time series. In [15] it is also required that $\mathsf{x}_i^1+\mathsf{l}_i^1$ is smaller than the the size of the time series, so that the whole subsequence referenced is included in the reference time series, and that $\mathsf{x}_i^0+\mathsf{l}_i^0<\mathsf{x}_i^1$, to avoid overlap between the subsequences and thus, the trivial solution where one of the subsequences is contained in the other. We will start by following the same considerations, in order to compare with their results. Nevertheless, our aim is to achieve this behavior trough the acceleration, rather than verifying in each step that all conditions are satisfied.

Finally, we want to point out that the terminating condition for the main loop has been stated in such an ambiguous way deliberately. In general, one may consider that when there is no improvement in the global best value the loop should come to conclusion. Against this, can be argued that even if there is no change in the global optimal position for a few iterations, while there exist some agent whose position is improving, it could happen that eventually it gets to a better position than the best already found. It is also possible to defend the thesis that even if there is no improvement in any of the agents, it can be due to the randomness of the exploration. In any case, a compromise between these postures must be achieved, and the analysis of the particular optimality function and ambient space for the agents is of great importance in this task.

3 Variations in the Acceleration and Optimality functions

As we have seen in the previous section, one of the key steps of the PSO algorithm is the computation of the optimality function, since it is there where the general algorithm is fitted to solve a specific problem. Nevertheless, the way in which the information acquired with this computation is used to dictate the movement of the agents may also affect the performance of the PSO. In this section we will address this two aspects of the implementation of the PSO algorithm.

3.1 Movement of the agents in the swarm

In a usual PSO algorithm, the change in velocity is computed as a linear combination of the current velocity, the direction to the best position encountered by the agent and the

 ISBN: 978-84-617-8694-7

direction to the best position found by the swarm:

$$\mathsf{v}_i^{n+1}=\mathsf{A}\mathsf{v}_i^n + \mathsf{B}(\mathsf{x}_i^n\text{-}\mathsf{bvx}_i) + \mathsf{C}(\mathsf{x}_i^n\text{-}\mathsf{gvx})$$

and then, the position updated as

$$\mathsf{x}_i^{n+1}=\mathsf{x}_i^n+\mathsf{v}-i^{n+1}.$$

This formulation is reminiscent of the phenomenon it want to mimic, albeit it is not uncommon that the values of the weights are chosen either randomly, or *ad hoc*. Also, the independence of the step-size and the rate of change carries the potential for instability of the algorithm [6]. While this is not necessarily a problem, since PSO algorithms are usually intended to randomly explore the ambient space where the agents live, this approach may be missing some of the good features of swarm behavior, it could benefit from.

In Algorithm 1 we already propose a slight variation to the standard PSO algorithm so that it is more in accordance with the formulation of swarming models, maintaining the second order formulation of the movement [1, 7, 19]. The inclusion of the coefficient dt allows us to regulate how much the rate of change in position and velocity will affect the current values, and thus avoid jumping over a minimum of the optimality function. Also, we change the velocity through the computation of an acceleration, where the desired directions will be taken into account. This will provide us a more general framework where different interaction rules between the agents can be included, as well as some self-propulsion term which shall help as deal with the restrictions on the positions of the particle mentioned in the previous section. Furthermore, this will help us to properly balance the weight of all the desired effects on the rate of change of the velocity. We will define the acceleration as

$$\mathsf{dv}_i^{n+1} = \omega_{\mathsf{I}}\mathsf{INTERACTION}+\omega_{\mathsf{SP}}\mathsf{SELF\_PROPULSION}+\omega_{\mathsf{PB}}(\mathsf{x}_i^n\text{-}\mathsf{bvx}_i) + \omega_{\mathsf{gb}}(\mathsf{x}_i^n\text{-}\mathsf{gbx}),$$

with $\omega_{\mathsf{I}} + \omega_{\mathsf{SP}}\omega_{\mathsf{PB}}\omega_{\mathsf{GB}} = 1$. Strictly speaking, the two last terms should be included in the SELF_PROPULSION and the INTERACTION terms respectively, but we keep them a part due to their relevance. The SELF_PROPULSION term represents the preferred velocity of the agent, in absence of the rest of the swarm, and can be used to provide the agent with a natural desire to remain within the boundaries dictated by the series and avoid positions corresponding to overlapping subsequences. In this first approach, though, we will overlook this effect and set ω_{SP} to zero. With respect to the INTERACTION term, we will limit ourselves to a basic attraction effect, nudging the agents to converge in the same position. While this can be counterproductive, as it may lead to concentration in a local minimum of the optimality function, it also facilitates a thorough exploration of the whole ambient

 ISBN: 978-84-617-8694-7

space of the agents if they are suitably spread during the initialization.

Algorithm 2 Interaction rule based solely in attraction.

$$\mathrm{dv}_i \leftarrow \frac{1}{\mathsf{SWARM\_SIZE}} \sum_{i \neq j} (x_j - x_i)|x_i - x_j|^{\alpha}$$

3.2 Distances between time series subsequences

In the context of pattern recognition between the subsequences of time series, it is natural to adopt the distance between subsequences as a measure of how good the position of an agent is. However, although intuitively the concept of distance is very clear, when it comes to a precise definition, there are many notions of distance that can be used [16]. The choice of one over the other, may imply also a different way of understanding the agents and will yield drastically different results. At this moment, the reference distance to evaluate the efficiency of new measures is the *Dynamic Time Warping* (see [14]). Our objective at this stage is not to provide a similarity measure that outperforms the currently available ones, but rather to explore how the choice of a distance affects not only the performance of the algorithm, in terms of speed, but also the behavior of the agents themselves, favoring the exploration of different regions.

With this idea in mind we propose two simple similarity functions. The first one is defined in the setting given in Section 2:

Algorithm 3 Direct comparison similarity function.

function DCDistance(AGENT, TS) ▷ TS is the time series that we want to study
  $seq1$ =TS([x^0,x^0+l^0])
  $seq2$ =TS([x^1,x^0+l^1])
  D=l^1-l^0 ▷ Assuming $l^1 > l^0$
  for $k \leftarrow 0$ To D **do**
    $$dif_k = \sqrt{\frac{1}{l^0} \sum_{l=0}^{l^0-1} (seq1(l) - seq2(k+l))^2}$$
  end for
  return $\min_k\{dif_k\}$
end function

This measure is a direct extension of the usual euclidean distance for vectors. We allow to compare sequences of different lengths by comparing the smaller one with each of the

 ISBN: 978-84-617-8694-7

subsequences of the same length in the larger one, without penalizing the proportion of the larger one that we are not able to compare. To compensate the different sizes of the sequences that every agent is comparing, we divide the sum of squared differences by the amount of terms in that sum.

We propose a second measure, which requires a small modification in the way we understand the agents, or rather, the space where they will move. An agent will still be defined by its position, velocity, current value, best value and best position, but we will understand the position as a subset of $\mathbb{R}^4$. From now on, x^0, x^1 shall denote any time between the first and the last time stamp of the series and l^0, l^1 will be the lengths of time intervals starting at x^0, x^1 respectively. By disengaging the agents from the actual points in the series we gain freedom of movement, at the price of needing to locate the right points in the series to evaluate the optimality of each position.

Algorithm 4 Interpolation similarity function.

function IDistance(AGENT, TS)
  $L \leftarrow \mathrm{l}^1/\mathrm{l}^0$
  $seq1x$ = Time-stamps of the series such that $[\mathrm{x}^0,\mathrm{x}^0+\mathrm{l}_0] \subseteq [seq1x(0), seq1x(end)]$, shifted to the origin.
  $seq2x$ = Time-stamps of the series such that $[\mathrm{x}^1,\mathrm{x}^1+\mathrm{l}_1] \subseteq [seq2x(0), seq2x(end)]$, shifted to the origin and scaled by L.
  $seq1v$ = original values of the series corresponding to $seq1x$.
  $seq2v$ = original values of the series corresponding to $seq2x$ scaled by L.
  $dif \leftarrow 0$.
  for $i \leftarrow 1$ To LENGTH($seq1x$) **do** ▷ We assume that $seq1x$ is shorter than $seq2x$
    $p \leftarrow seq1x(i)$
    $v \leftarrow$ INTERPOLATE(pa, pb)
      ▷ pa and pb being the pairs (x_i2p, v_i2p), (x_i2n, v_i2n), where $i2p$ and $i2n$ is the index of the elements in $seq2x$ such that $x_i2p < p < x_i2n$.
    $dif \leftarrow dif + |seq1v(i) - v|$
  end for
  return $\dfrac{dif}{\mathrm{LENGTH}(seq1x)}$
end function

4 Results

In order to study the behavior of the method that we present in this work, we have implemented an program using the Python language, which allows the use of different objective functions. In this first version, we have used as objective function the distances DCDistance and IDistance detailed in Section 3.2.

IDistance is more directly inspired by [15]. We also encounter the overlapping issues that are mentioned there. Due to the lack of space, we omit a detailed description of the tests that we have tried and present directly the results that we have obtained together with the conclusions:

1. The algorithm always converges.

2. As we could expect, when one of the subsequences is contained in the other, the results of the PSO algorithm is better, since we are comparing a subsequence with a portion of itself.

3. Whenever the intersection of the two subsequences is not empty, the agents find that the optimal position lies in the direction that increases the overlapping. The smaller subsequence is *absorved* by the larger one. Some authors advise against allowing this to happen (see for instance [15]). As we mentioned in the introduction, to enforce this restriction a control must be kept through all the execution of the code, since, if the subsequences are close enough, an overlapping may happen, even if initially there are no intersections.

4. Occasionally, the agents show a *static* behavior. By this we mean that the position of the agent only changes very slightly, i. e., the subsequences that it is comparing remain the same. This happens when the random initialization generates an agent in a position corresponding to big overlapping.

5. When the agents are instantiated in positions corresponding to far enough subsequences, the PSO algorithm terminates before reaching and acceptable optimal. We want to point out that this happens because there has been no improvement in the best value of any of the agents, which indicates that this distance should not be used as a measure of optimality.

As an example of test, we present the results obtained with a swarm of five agents. We have generated the agents with random positions. Four of them correspond to subsequences which do not overlap, while the fifth shows a strong overlapping.

 ISBN: 978-84-617-8694-7

Table 1: Test of the PSO algorithm with DCDistance.

Iter		P_1	P_2	P_3	P_4	P_5
0	xb_1	$[489, 199, 966, 119]$	$[689, 83, 918, 190]$	$[860, 182, 445, 135]$	$[200, 118, 78, 154]$	$[342, 217, 963, 96]$
	bv_1	100.3341	49.9639	60.3542	0.5226	77.5270
5	xb_5	$[484, 195, 954, 119]$	$[689, 83, 918, 190]$	$[853, 179, 441, 135]$	$[200, 118, 78, 154]$	$[338, 213, 951, 96]$
	bv	94.1980	49.9639	59.9998	0.5226	70.1617
10	xb_{10}	$[472, 190, 922, 119]$	$[689, 83, 918, 190]$	$[837, 175, 431, 135]$	$[200, 118, 78, 154]$	$[331, 208, 919, 96]$
	bv_{10}	75.7245	49.9639	59.6598	0.5226	49.0530
15	xb_{15}	$[458, 186, 883, 119]$	$[689, 83, 918, 190]$	$[837, 175, 431, 135]$	$[200, 118, 78, 154]$	$[327, 206, 902, 96]$
	bv_{15}	53.2119	49.9639	59.6595	0.5226	39.16991

This results in a fast convergence of the algorithm, needing just fifteen iterations. Table 1 shows the results. We show an iteration in every five. In each iteration we will expose the best positions and best values obtained by each agent. This table allows us to study the path of descent to the optimal position followed by the agents.

Next, focus on the results obtained with the second distance function studied.

1. This function does not strengthen the preference of the agents for positions corresponding to overlapping between subsequences. This is a consequence of comparing the subsequences as a whole.

2. In the same line as the previous remark, it is rare to find an overlapping, and when one occur, the position does not benefit from it through this distance.

3. The battery of tests is insufficient to assert the good performance of the PSO algorithm using this distance as the objective function. Nevertheless, we have usully obtained an optimal value close to 0.5, which is encouraging.

As with the distance DCDistance, we want to present a test done using IDistance as the objective function. We describe the results in the following table, which is structured in the same way as Table 1:

We show an iteration in every seven. The test converges in fifty-seven iterations. We want to stress that, contrary to what happen using DCDistance as objective function, even if the starting position is bad, all agents will explore the ambient space, and find a path to a position comparable with the best position of the swarm.

5 Conclusions

We have modified the usual PSO algorithm to allow a larger interaction between the agents and applied it to the study of patterns within time series. We have considered two (naive) similarity functions and confirmed how strongly the behavior of the agents depends on how the distance between subsequences is understood. The distance DCDistance presents serious issues concerning convergence; it shows a strong tendency to select as optimal the trivial solutions where there is a strong overlapping between subsequences. The distance IDistance shows promising results. From the tests done, the evident trivial optimal states have a negligibly small basin of attraction.

Abstract

In this paper, a statistical procedure for automatically generating textual reports from thermal comfort data is proposed. These reports provide design engineers with useful information to keep adequate comfort level conditions for occupants in buildings. In order to show and explore the possibilities of this procedure, we have implemented a software prototype called YADY for Thermal Comfort.

Key words: Summarization of data, Thermal Comfort Data, Textual Reports, Statistical Procedure, Software Application

1 Introduction

Thermal comfort in buildings has become a main research topic in recent years, since it allows designers to maintain adequate comfort level conditions through passive measures, hence reducing energy consumption [3, 7]. To this end, designers usually employ software applications to simulate a building model in order to obtain comfort predictions. However, the amount of data generated by such applications is extremely large and its correct interpretation becomes a complex task [1, 4]. In addition, the data generated by simulation software is used to identify certain behavioral patterns and to predict future trends.

 ISBN: 978-84-617-8694-7

In this paper, a method to overcome these difficulties on interpreting comfort simulation results is proposed. The use of linguistic data summaries has been identified as a possible solution, which can provide HVAC (heating, ventilation, and air conditioning) design engineers with a better and easier understanding of the results obtained. For example, data summaries have been employed for automatically generating advice for saving energy at home [2].

In particular, an automatic generation of textual reports as a translation of the data provided by the simulation software is implemented in order to provide design engineers with knowledge about particular situations that occur in the building in a particular time span (i.e. annually, monthly, daily, and other personalized time spans). Below, examples of the reports generated are shown:

- **Annual Report:** "*During this year (8760 hours), the building was in a comfort situation with a ratio of 60%; 10% of the time, the building was in a discomfort situation (180 hours over comfort temperatures and 240 under comfort temperatures). The rest of the time (30%), it was in a slightly cold situation during 430 hours and in a slightly warm situation during 608 hours. The months with the highest ratio of comfort situations were December, January, February and March with an average of 80%; the months with the lowest ratio of comfort situations were June, July and August with an average of 50%. In the rest of the months, the average of comfort situations, was 60%*".
- **Monthly Report:** "*In January, the number of comfort situations detected had an acceptable ratio of 75%. There were slightly cold situations covering 20 hours and slightly hot situations for 30 hours. The best days were the 16th, 18th, 19th and 20th, with a ratio of 90% in acceptable conditions. The worst days were the 1st, 2nd and 3rd, with a 60% ratio of discomfort situations. Cold conditions are usually produced between 2am and 9am, with an outdoor average temperature of* $6°C$*. Warm conditions are usually produced between 3pm and 7pm, with an average outdoor temperature of* $32°C$".
- **Daily Report:** "*For the day 07/07, comfort conditions were detected with a 75% ratio; there were cold situations over 2 hours and a little bit of warm for 1 hour. Discomfort situations were usually detected between 2am and 9am, with an average exterior temperature of* $6°C$".
- **Personalized Report:** "*In January, comfort conditions were maintained with a ratio of 75%. Some cold situations were detected covering 20 hours, while a few warm situations were detected covering a total of 30 hours*".

A statistical procedure for the linguistic summarization of thermal comfort data is here proposed. The report, which is conveyed in a linguistic style, can be easily included as a narrative component in other applications with the same objective. The structure of the paper is as follows. In Section 2, the procedure to automatically generate linguistic reports from thermal comfort data is presented. Section 4 gives details about the implementation and experimentation. Finally, in Section 5 conclusions and future lines of work are drawn

 ISBN: 978-84-617-8694-7

from the present study.

2 Procedure for automatically generating linguistic reports from thermal comfort data

The proposed procedure aims to determine which is the comfort situation of the building (cold, sightly cold, comfort, sightly warm, or warm)in a particular period of time (annually, monthly, daily). To this end, the adaptive thermal comfort model defined in the standard EN 15251 [5] is employed, where a set of variables is used in order to infer a particular situation. These variables are called comfort metrics, and are the following:

- Daily Average Temperature (DAT)
- Weighted Average Temperature (WAT)
- Operative Temperature (OP_EN)
- Upper Limit of Category I (Upper L1)
- Lower Limit of Category I (Lower L1)
- Upper Limit of Category III (Upper L3)
- Lower Limit of Category III (Lower L3).)

The procedure starts reading the data exported by the simulation tools or importing the data from an intermediate file (XLS) (see Table 1). The input variables are: Date-Hour, Indoor Operative Temperature, and Outdoor Air Temperature.

Table 1: Input data exported, table T

Id	Date-Hour	Indoor Operative Temperature	Outdoor Air Temperature
1	01/01/2002 1:00	23,97483	13,35
2	01/01/2002 2:00	23,34624	12,2
3	01/01/2002 3:00	22,8341	11,4
...	...	...	...
8760	31/12/2002 24.00	24,84875	13,8

After that, Algorithms 1, 2, 3 and 4 (see Appendix) have been designed and implemented in order to compute the values for each comfort metric based on EN 15251 (see Table in Figure 1).

 ISBN: 978-84-617-8694-7

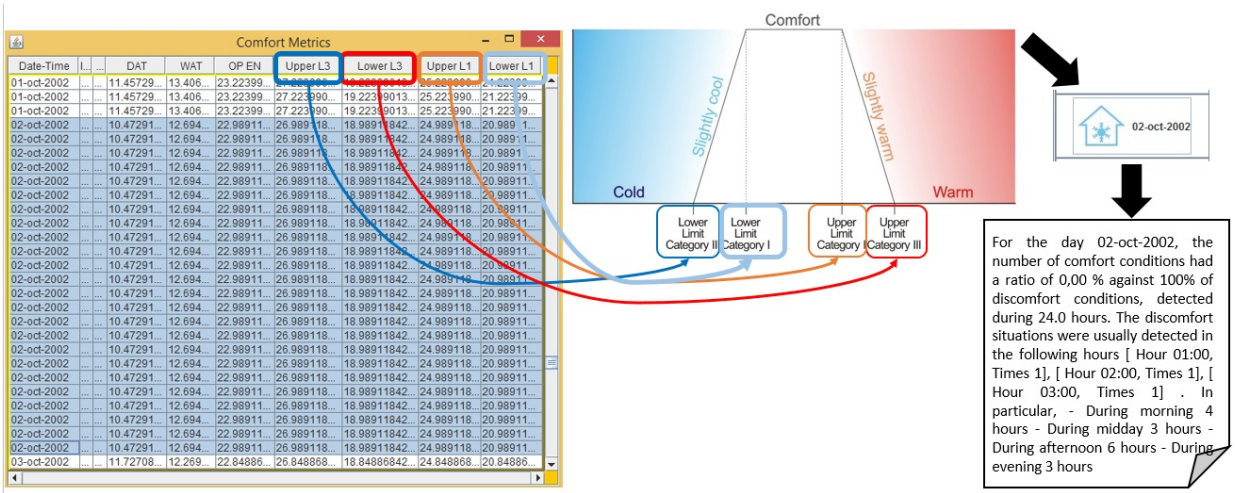

Figure 1: Data generated by means of the comfort model and the computation of a particular comfort situation based on the categories proposed in the model EN 15251

The table shown in Figure 1 contains the values for each comfort metric. A new database containing only two attributes is then created: $R_i = \{\text{date, current situation of comfort }\}$. Each row has the form: $R_i : D_i\{cold \mid slightly\_cold \mid comfort \mid slightly\_warm \mid warm\}$, where only one value can appear in each row, that is, the symbol "|" is acting as the conjunction "or". The reduced database has the following form:

```
R 1 : D 1 [cold | slightly cold | comfort | slightly warm | warm]
R 2 : D 2 [cold | slightly cold | comfort | slightly warm | warm]
...
R N : D N [cold | slightly cold | comfort | slightly warm | warm]
```

However, the ratio of comfort, discomfort and borderline (slightly cold and warm) situations have to be computed and arranged by day, month and year. From the existing database, the total number of cold, slightly cold, comfort, slightly warm and warm situations can be computed by counting the frequency of occurrence in each R_i. Therefore, the ratio is obtained as the summation of the number of a particular figure over the total number of situations detected, which are defined as follows: RATIO_COLD, RATIO_SIGHTLY_COLD, RATIO_COMFORT, RATIO_SIGHTLY_WARM, and RATIO_WARM. These ratios represent the percentage for each situation during a given year.

Now, as each D_i has the form "day-month-year" a sub database that represents either a year, a month or a day can be generated. For example, given "$D_i = d - m - y$", a sub database for "$m - y$", that is, for a particular month can also be generated:

```
R1: [m-y] [cold | slightly cold | comfort | slightly warm | warm]
```

 ISBN: 978-84-617-8694-7

```
R2: [m-y] [cold | slightly cold | comfort | slightly warm | warm]
...
Rk: [m-y] [cold | slightly cold | comfort | slightly warm | warm]
```

In this case, the ratio of comfort, discomfort and borderline (slightly cold and warm) situations are computed for a particular month (m). In the same way, the ratio can also be obtained as the summation of the number of a particular time span over the number total of situations that were detected in a month. These ratios represent the percentage for each situation during a particular month. Additionally, the linguistic report is also able to convey information about an important matter: the best and the worst months during a given year.

3 Reports Template

In this research, four types of reports are generated, namely annual, monthly, daily and personalized. Only first one will be hereby explained in detail, since the rest them are analogously created.

The Annual Report Template is based on the pattern explained in the introduction. This report template has been created in order to provide designers with the most relevant details about the comfort and discomfort situations during a particular year. The process of automatically creating an annual report requires a link to the annual report template that contains the ratio of comfort situations ($RATIO\_COMFORT$), the ratio of discomfort situations ($RATIO\_COLD + RATIO\_WARM$), and the ratio of both slightly cold and slightly warm situations ($RATIO\_SIGHTLY\_COLD + RATIO\_SIGHTLY\_WARM$).

Additionally, the number of hours where the temperature was above the comfort temperature (O), the number of hours where the temperature was below the comfort temperature (U), the number of hours where the temperature was slightly cold (SC) and slightly warm (SW), and the best M_i and worst M_j months should be linked by the report template module. Hence, the report template is defined as follows:

During the year [Ye], the building was in a [COMFORT | DISCOMFORT] situations with a ratio of [X] per-cent, only [Y] per-cent of the time it was in a [COMFORT | DISCOMFORT]** situations ([O] hours over the comfort temperature, [M] hours under the comfort temperatures). The rest of the time it was in a [SLIGHTLY WARM | SLIGHTLY COLD]* during [SC | SW]* and [SLIGHTLY WARM | SLIGHTLY COLD]* during [SC | SW]* hours. The rest of the ratios were the following: [Ratio Cold; Ratio Sightly Cold; Ratio Sightly Warm; Ratio Warm]. The best month was M_i with a comfort ratio of [B]. The worst month was M_j with a discomfort ratio of [W]*

Note that, X1= [a—b] * X2= [a—b] ** means that if X1=a then X2=b, and if X1=b then X2=a. The annual report template could also be restricted to query about a particular

 ISBN: 978-84-617-8694-7

season: “During the [winter | spring | autumn | summer], the situation of the building was [cold | slightly cold | comfort | slightly warm | warm]”.

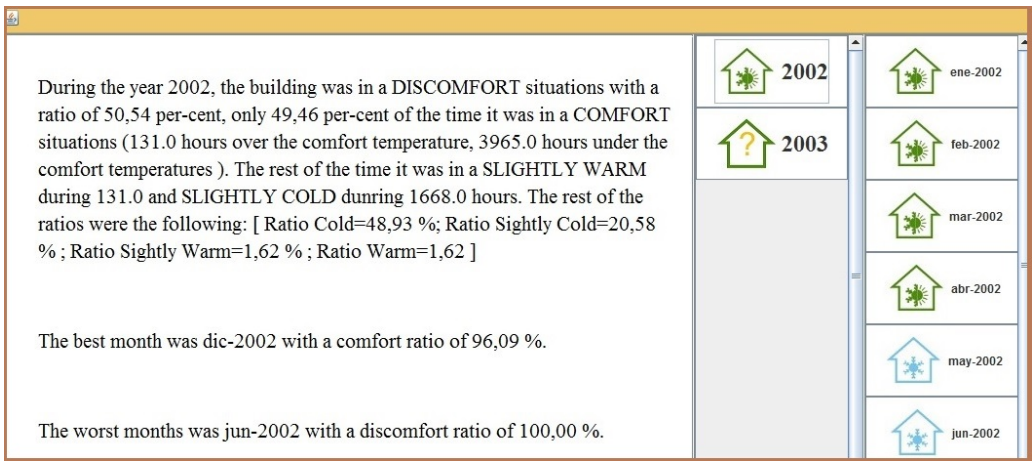

Figure 2: Automatically data generated annual Linguistic report

4 Implementation and Experimentation

YADY (”Your actions define you”) is a new technology whose objective is to get automated behavior recognition from the actions performed by entities interacting in a dynamic environment. This environment is usually modeled by physical parameters, which can be captured by using sensors, electronic devices, biometric tools and so on. This kind of environment is modified by its entities. Well-established metrics can be used to measure these changes. Next, a relationship can be established between these different entities by using linguistic terms. Linguistic terms allow us to express these numerical metrics and relationships in words. This automated behaviour recognition can be applied to many systems, depending on the application-context. As a first approach, YADY technology has been applied to improve players’ experience in computer games (Rubio-Manzano and Trivino 2016).

In this paper, this technology has been adapted and applied to automatically generate linguistic descriptions in the scientific field of thermal comfort. The behavior of a building with regards to the thermal comfort can be inferred by analyzing the data captured by the simulation tool. The procedure presented in the previous sections has been implemented in the application “YADY Thermal Comfort Tool”, which can be downloaded using the URL: `http://youractionsdefineyou.com/yady_tc/`. This software tool has been implemented by using the Java programming language.

As a result, the experiment generates three reports, one for each type. From an input

 ISBN: 978-84-617-8694-7

file, the user can generate all desired reports for a particular period of time, just by indicating the granularity: year, month or day.

The user interface for annual reports allows users to visualize an automatically generated report for a particular year. On the right side of the screen, users can see if discomfort situations occurred, and also click on it for more details about this phenomenon (Figure 2). This interface works in an analogous way for monthly and daily reports.

5 Conclusions and future work

In this study, a procedure for automatically generating textual reports from thermal comfort data has been presented. A software application based on this procedure, which is able to generate building's comfort use reports from comfort metrics, has been developed. This new resource provides designers with useful information regarding adaptive thermal comfort assessment.

This work is a first approximation towards a broader approach, and much work remains to be done in this direction. The proposed model is simple and effective in showing all the potential of natural language as a feedback mechanism for building designers.

Research on how this procedure could be implemented by using Linguistic Description of Complex Phenomena could represent an interesting future line of work. Therefore, a comparison between crisp and fuzzy paradigms is an important challenges for us.

Appendix: Algorithmms

Algorithm 1: Algorithm for the creation of the database for comfort situations

```
1 begin

Abstract

Surveys usually include sensitive topics as such as gambling, alcoholism, sexual behavior, domestic violence which characteristics are difficult to estimate using standard survey techniques because of the tendency of respondents to hold information in such settings. On the other hand, multiple frame surveys are becoming a widely used method to decrease bias due to undercoverage of the target population. In this work, we consider statistical techniques for handling sensitive data coming from a multiple frame survey using complex sampling designs. Our aim is to estimate the mean of undesirable behaviors when data are obtained by using a randomized response technique. Some estimators are constructed and their properties theoretically investigated. We also derive variance estimators.

Key words: complex surveys, randomized response techniques, multiple frames, calibration.
MSC 2000: AMS 62D05

1 Introduction

In socioeconomic or biomedical studies, very often the researcher has to gather information relating to highly sensitive issues. In these situations, posing direct questions to the respondents may procure untruthful responses or even refuse to respond because of social stigma or fear about threat of disclosure.. Such systematic response errors lead to social-desirability bias in estimates of the sensitive behaviors of interest, underestimating socially undesirable activities.

To overcome these problems, methods such as the randomized response (RR) technique (RRT) may be used to collect more reliable data, protect respondent's confidentiality and

 ISBN: 978-84-617-8694-7

avoid unacceptable rate of nonresponse. In the RRT, respondents use a randomization device to generate a probabilistic relationship between their answers and the true values of the sensitive characteristic. The RRT has been applied in surveys covering a variety of sensitive topics like racism, drug use, abortion, delinquency or AIDS.

The RRT was originated by Warner (1965) who proposed a data collection procedure that allows researchers to obtain sensitive information while guaranteeing privacy to respondents. Warner's study generated a rapidly-expanding body of research literature on alternative techniques for eliciting suitable RR schemes in order to estimate proportions, means or totals. A good review of different RR procedures is given in Chaudhuri and Christofides (2013) and Chaudhuri et al. (2016).

Traditionally, surveys have been carried out using three main methods of data collection: face-to-face interviews, mail surveys and telephone interviews. Over the last 20 years, the picture has changed sharply. Telephone surveys have become a popular mode of data collection, especially following the creation and development of computer-assisted telephone interviewing (CATI) systems. However, telephone surveys also present some drawbacks with regard to coverage, due to the absence of a telephone in some households and the generalized use of mobile phones, which are sometimes replacing fixed (land) lines entirely. The potential for coverage error as a result of the exponential growth of the cell phone-only population has led to the development of dual-frame surveys. Surveys where data are collected from three sampling frames are also used in practice. The popularity of multiple frame surveys has increased among scientific community along last years and now they are widely used both in statistical agencies and in private organizations. In the near future, importance of three frame surveys is expected to grow with the use of the internet for data collection (Lohr, 2010). Indeed, it is very likely that dual frame surveys consisting of a cell and a landline frame evolve to three frame surveys incorporating a third frame of web users. However, there are very few studies that address the problem of estimating sensitive behaviors from two frames. Recently Rueda et al. (2015) proposed some dual frame estimators for proportions and mean when the data are obtained by using the RRT. The aim of this paper, thus, is to propose new estimation techniques for sensitive parameters when data come from more than two frames.

2 Some generalities of estimation in multiple frames

We will employ the notation used in Mecatti (2007). Let U be a finite population composed of N units labeled from 1 to N, $U = \{1, ..., k, ..., N\}$ and let $A_1, \ldots, A_q, \ldots, A_Q$ be a collection of $Q \geq 2$ overlapping frames of sizes $N_1, \ldots, N_q, \ldots, N_Q$, all of them can be incomplete but it is assumed that overall they cover the entire target population U. With Q frames, there are $2^Q - 1$ possible distinct domains. Let the index sets K be the subsets of the range of the frame index $q = 1, \ldots, Q$. For every index set $K \subseteq \{1, \ldots, q, \ldots, Q\}$ a

 ISBN: 978-84-617-8694-7

domain is defined as the set $D_K = (\cap_{q\in K} A_q) \bigcap (\cap_{q\notin K} A_q^c)$, where ^{c} denotes the complement of a set (that is, D_K is the subset of units that are covered by all the frames A_q, $q \in K$, and by these frames only). Let y be a sensitive variable to study which cannot be observed directly. The objective is to estimate the population mean of y that is

$$\overline{Y} = \frac{1}{N} \sum_{k\in U} y_k, \tag{1}$$

where y_k is the value of the sensitive character for the k-th unit. This mean can be rewritten as follows

$$\overline{Y} = \frac{1}{N} \sum_{q=1}^{Q} \sum_{k\in A_q} \frac{y_k}{m_k}, \tag{2}$$

where m_k indicates the multiplicity of the k-th unit, i.e. the number of frames the unit k is included. Multiplicities m_k are needed in (2) to weight values y_k, otherwise, those units belonging to more than one frame would count more than once in the overall sum.

Let s_q be a sample drawn from frame A_q under a particular sampling design, independently for $q = 1, \ldots, Q$ and let $\pi_k(q)$ and $\pi_{kl}(q)$ be the first and second order inclusion probabilities under this sampling design, respectively. Let $d_k(q) = 1/\pi_k(q)$ be the sampling weight for units in frame q. Moreover, let n_q be the size of sample s_q and $s = \cup_q s_q$.

Lohr and Rao (2006) formulated the multiple frame extension of some of the estimators originally proposed for the dual frame case, as the one proposed by Hartley (1962, 1974) or by Fuller and Burmeister (1972). Although the optimal version of these estimators is asymptotically efficient, it is not internally consistent since a different set of weights is used for each response variable. Moreover, it is often unstable in small or moderate samples with more than two frames because the optimal estimated parameters involved in the computation of the estimators are functions of large estimated covariances matrices. Lohr and Rao (2006) also followed the so called single frame approach used by Kalton and Anderson (1986) to proposed a single frame estimator in a multiple frame context. This estimator is in the form:

$$\hat{\overline{Y}}_{KA} = \frac{1}{N} \sum_{k\in s} y_k d_k^{KA} \tag{3}$$

with $d_k^{KA} = \bar{\pi}_k^{-1}$, where $\bar{\pi}_k = \sum_{q'\ni k} \pi_k(q')$ where $q' \ni k$ denotes the sum for the frames containing to the unit k. To compute this estimator it is necessary to know not only the number of frames each unit belongs to, but also the specific frames the unit is included in. This can be an important drawback particularly if misclassification issues are present.

Lohr and Rao (2006) also proposed the following pseudo-maximum likelihood estimator for the multiple frame context:

$$\hat{\overline{Y}}_{PML} = \frac{1}{N} \sum_{k\in s} y_k d_k^{PML}(q), \tag{4}$$

 ISBN: 978-84-617-8694-7

where the weights d_k^{PML} can be defined as

$$d_k^{PML}(q) = d_k(q) f(q) \sum_{K:q\in K} \frac{\hat{N}_K \delta_k(K)}{\sum_{j\in K} f(j)\hat{N}_K(j)}$$

with $f(q) = \frac{1}{deff_z(q)} \frac{n_q}{N_q}$, being $deff_z(q)$ the design effect for variable z in the q-th frame. Values $\hat{N}_K(q)$ can be computed as $\hat{N}_K(q) = \sum_{k\in s_q} d_k(q)\delta_k(K)$, with $\delta_k(K)$ the indicator variable for domain K that takes the value 1 whether unit k belongs to domain K and 0 otherwise. The estimated domain sizes $\hat{N}_K$ are the solution of a system of non linear equations. The pseudo maximum likelihood is consistent and usually works well in practical situations but it is complex to compute for a general sampling design, since numerical procedures are required to obtain the values $\hat{N}_K$.

Mecatti (2007) also considered a single frame approach and proposed the following estimator

$$\hat{\bar{Y}}_M = \frac{1}{N} \sum_{k\in s} y_k d_k^M, \tag{5}$$

with $d_k^M = d_k/m_k$. The previous estimator, often called single frame multiplicity estimator, only requires the knowledge of the multiplicity of each unit, no matter which these frames are. This estimator can be adjusted using a raking ratio approach to get a single frame raking ratio multiplicity estimator where a new set of weights, resulting from an iterative procedure, is used.

Singh and Mecatti (2011) proposed a composite multiplicity estimator, which generalizes the single frame multiplicity estimator. This estimator can be written as

$$\hat{\bar{Y}}_{CM} = \frac{1}{N} \sum_{k\in s} y_k d_k^{CM} \tag{6}$$

where

$$d_k^{CM} = \frac{\lambda_k d_k + (1-\lambda_k) d_k^{KA}}{m_k}$$

with

$$\lambda_k = \frac{\sum_{q'\ni k}(1 - \bar{\pi}_k/\pi_k(q'))\pi_k(q')(1-\pi_k(q'))}{\sum_{q'\ni k}(1 - \frac{\bar{\pi}_k^2}{\pi_k(q')^2} - \frac{2\bar{\pi}_k}{\pi_k(q')})\pi_k(q')(1-\pi_k(q'))}.$$

Usually, additional information about auxiliary variables is available in surveys. Rao and Wu (2010) followed a single frame multiplicity based approach to extend the pseudo empirical likelihood estimator for the mean of a variable to the multiple frame setting. Calibration is also a well-known technique to deal with auxiliary information in estimation. Ranalli et al. (2016) proposed different calibration estimators for the dual frame case, which can be easily extended to the multiple frame context. Rueda et al. (2017) proposed model-assisted estimators for population proportions in multiple frames.

 ISBN: 978-84-617-8694-7

3 Randomized response techniques for multiple frames

We assume that the variable under study y cannot be observed directly and that in each frame it is possible to use a different RR procedure to collect data on it. In order to consider a wide variety of RR devices, we consider the unified approach given by Arnab (1996) according to the individuals in the sample s_q use a generic RR model denoted by RR_q. For each $k \in s_q$ the RR_q induces a random variable Z_{qk} so that the revised randomized response R_{qk} is an unbiased estimation of y_{qk}, the real value of the sensitive variable for the k-th unit in s_q. We consider RR_q, with $q = 1, ...Q$, to be independent randomized devices such that the respective revised randomized responses R_{qk} satisfy the conditions (see Arnab, 2004) $E_R(R_{qk}) = y_k$, $V_R(R_{qk}) = \sigma^2_{qk}$, $C_R(R_{qk}, R_{qj}) = 0$, where E_R, V_R and C_R denote the expectation, variance and covariance operators with respect to the RR mechanism.

Using the idea of Mecatti (2007) we propose the multiplicity estimator

$$\hat{\bar{Y}}_{RM} = \frac{1}{N} \sum_{q=1}^{Q} \sum_{k \in s_q} R_{qk} d_k^M(q), \tag{7}$$

with $d_k^M(q) = d_k(q)/m_k$.

4 Properties of the proposed estimator

In this section we describe the main properties of the proposed estimator.

Theorem 1. The multiplicity estimator $\hat{\bar{Y}}_{RM}$ is an unbiased estimator of the population mean $\overline{Y}$

Proof.

Let E_d and V_d denote the expectation and variance operators for any sampling design d. Hence, we have:

$$E(\hat{\bar{Y}}_{RM}) = \frac{1}{N} E_d E_R \left(\sum_{q=1}^{Q} \sum_{k \in s_q} R_{qk} d_k^M(q) \right) =$$

$$\frac{1}{N} E_d \left(\sum_{q=1}^{Q} \sum_{k \in s_q} E_R(R_{qk}) d_k^M(q) \right) = \frac{1}{N} E_d \left(\sum_{q=1}^{Q} \sum_{k \in s_q} y_{qk} d_k^M(q) \right) =$$

$$\frac{1}{N} \sum_{q=1}^{Q} E_d \left(\sum_{k \in s_q} y_{qk} d_k^M(q) \right) = \frac{1}{N} \left(\sum_{q=1}^{Q} \sum_{k \in A_q} y_{qk} \right) = \overline{Y}$$

Then, $\hat{\bar{Y}}_{RM}$ is an unbiased estimator of the population mean.

 ISBN: 978-84-617-8694-7

Theorem 2.
The variance of $\hat{\hat{Y}}_{RM}$ *is given by*

$$V(\hat{\hat{Y}}_{RM}) = \frac{1}{N^2}\left(\sum_{q=1}^{Q}\sum_{k\in A_q}\sigma_{qk}^2 d_k^M(q) + \sum_{q=1}^{Q}\sum_{k\in A_q}\sum_{j\in A_q} y_k y_j (d_k^M(q) d_j^M(q)\pi_{kj}(q) - 1)\right). \quad (8)$$

Proof. By using the properties of the Horvitz-Thompson estimator (Särndal et al. 1992), we have:

$$V(\hat{\hat{Y}}_{RM}) = E_d V_R(\hat{\hat{Y}}_{RM}) + V_d E_R(\hat{\hat{Y}}_{RM}) =$$

$$\frac{1}{N^2}\left(E_d\left(\sum_{q=1}^{Q}\sum_{k\in s_q} V_R(R_{qk})(d_k^M(q))^2\right) + V_d\left(\sum_{q=1}^{Q}\sum_{k\in s_q} E_R(R_{qk}) d_k^M(q)\right)\right) =$$

$$\frac{1}{N^2}\left(\sum_{q=1}^{Q}\sum_{k\in A_q} V_R(R_{qk})(d_k^M(q))^2\pi_k(q) + \sum_{q=1}^{Q}\sum_{k\in A_q}\sum_{j\in A_q} y_k y_j (d_k^M(q) d_j^M(q)\pi_{kj}(q) - 1)\right) =$$

$$\frac{1}{N^2}\left(\sum_{q=1}^{Q}\sum_{k\in A_q}\sigma_{qk}^2 d_k^M(q) + \sum_{q=1}^{Q}\sum_{k\in A_q}\sum_{j\in A_q} y_k y_j (d_k^M(q) d_j^M(q)\pi_{kj}(q) - 1)\right).$$

Hence the proof.

The variance of the estimator is composed of two terms which are common to all of the RR models. The second addendum depends on the sampling designs d_q and the y_k values in each frame. It denotes the variance of the Horvitz-Thompson estimator computed on the true values of y. The first term depends on the sampling designs and also on the randomization mechanism used in each frame. It represents the cost to pay, in terms of efficiency, to increase respondents' confidentiality.

In the formulation of the proposed estimators it is assumed that the population size N is known and Horvitz-Thompson estimator is used as baseline. Alternatively, one can consider Hájek-type estimators substituting N with $\hat{N}$, an unbiased design-based estimator of N. This is a special case of ratio estimator, and it can be more efficient than Horvitz-Thompson type estimators because the sample size in overlapping domains is not fixed. The estimators are thus approximately unbiased under certain conditions on the weights (see Lohr, 2009).

 ISBN: 978-84-617-8694-7

5 Variance estimation

Let $\hat{\sigma}^2_{qk}$ be an unbiased estimator of σ^2_{qk}. Hence, it can be proved that an analytical unbiased estimator of $V(\hat{\bar{Y}}_{RM})$ is given by:

$$\hat{V}(\hat{\bar{Y}}_{RM}) = \frac{1}{N^2}\left(\sum_{q=1}^{Q}\sum_{k\in s_q}\hat{\sigma}^2_{qk}d^M_k(q) + \sum_{q=1}^{Q}\sum_{k\in s_q}\sum_{j\in s_q} R_k R_j d^M_k(q) d^M_j(q)\left(1-\frac{\pi_k(q)\pi_j(q)}{\pi_{kj}(q)}\right)\right).$$

To define the estimator $\hat{V}(\hat{\bar{Y}}_{RM})$ we need $\pi_{kj}(q)$ for all units in each frame. In some common sampling designs (as cluster sampling with probability proportional to size) these probabilities are unknown or can be equal to 0 for some sampling units i, j. A simple alternative is the use of with replacement variance estimators (see Särndal et al.(1992), p. 99) or replicated sampling methods (see Wolter (2007) for a detailed description of these techniques in finite population sampling). Quenouille (1949) introduced the jackknife method to estimate the bias of an estimator by deleting one datum each time from the original data set and recalculating the estimator based on the rest of the data. In survey sampling it is usual to use jackknife techniques due to their simplicity and because they are implemented in general purpose software packages, such as R.

The last terms in (8),

$$\frac{1}{N^2}\sum_{q=1}^{Q}\sum_{k\in A_q}\sum_{j\in A_q} y_k y_j (d^M_k(q) d^M_j(q)\pi_{kj}(q) - 1) = V_{HT}$$

is a Horvitz-Thompson variance estimator with weights $d^M_k(q)$. If we consider a non-stratified design, the jackknife estimator for V_{HT} may be given by

$$v_J(\hat{V}(\hat{\bar{Y}}_{RM})) = \sum_{q=1}^{Q}\frac{n_q-1}{n_q}\sum_{i\in s_q}(\hat{\bar{Y}}_{RM}(i)(q) - \bar{Y}_{RM}(q))^2, \tag{9}$$

where $\hat{\bar{Y}}_{RM}(i)(q)$ is the value taken by estimator $\hat{\bar{Y}}_{RM}$ after eliminating unit i from s_q and $\bar{Y}_{RM}(q)$ is the average of $\hat{\bar{Y}}_{RM}(i)(q)$ values.

It is known that the jackknife variance estimator is asymptotically design unbiased for the variance of Horvitz-Thompson estimator (Wolter, 2007). So for the large sample size n we have $E(v_J(\hat{V}(\hat{\bar{Y}}_{RM}))) = V_{HT}$. Thus the adapted jackknife estimator

$$v_J(\hat{V}(\hat{\bar{Y}}_{RM}))^* = \sum_{q=1}^{Q}\frac{n_q-1}{n_q}\sum_{i\in s_q}(\hat{\bar{Y}}_{RM}(i)(q) - \bar{Y}_{RM}(q))^2 + \frac{1}{N^2}\left(\sum_{q=1}^{Q}\sum_{k\in A_q}\hat{\sigma}^2_{qk}d^M_k(q)\right)$$

is an unbiased estimator for the variance of the proposed estimator.

 ISBN: 978-84-617-8694-7

6 Estimation with auxiliary information

Usually, population level information about auxiliary variables is available in surveys. Let $\mathbf{x}_q = (x_{q1}, x_{q2}, \ldots, x_{qp_q})'$ be a set of p_q auxiliary variables observed in the q-th frame, so that the vector $\mathbf{x}_{qk} = (x_{q1k}, x_{q2k}, \ldots, x_{qp_qk})'$ includes the values taken by the variables $\mathbf{x_q}$ on the k-th unit in frame A_q. That is, we consider the case of complete auxiliary information. In addition, we consider the more general case in which auxiliary variables may differ in each frame, i.e. $\mathbf{x_q} \neq \mathbf{x_r}$, for $q, r = 1, \ldots, Q, q \neq r$. For the sample selected from frame A_q, the values of the variables $\{y_k, \mathbf{x}_{qk}\}$ are observed.

Calibration (Deville and Särndal, 1992) is also a well-known technique to deal with auxiliary information in estimation. Some works link RR models and calibration techniques together (Tracy and Singh (1999); Diana and Perri (2012)).

Ranalli et al. (2016) proposed different calibration estimators for the dual frame case. Using this idea we define a calibration estimator for randomized response to the multiple frame context. A calibration estimator in the case of several sampling frames can be defined as

$$\hat{\bar{Y}}_{CAL} = \frac{1}{N} \sum_{q=1}^{Q} \sum_{k \in s_q} d_k^{CAL}(q) R_k, \tag{10}$$

where $d_k^{CAL}(q)$ are such that they minimize $\sum_{q=1}^{Q} \sum_{k \in s_q} G\left(d_k^{CAL}(q), d_k^M(q)\right)$, where $G(\cdot, \cdot)$ is a particular distance function, subject to

$$\sum_{q=1}^{Q} \sum_{k \in s_q} d_k^{CAL}(q) \delta_k(A_q) = N_q, \quad q = 1, ..., Q$$

$$\sum_{q=1}^{Q} \sum_{k \in s_q} d_k^{CAL}(q) \mathbf{x}_{qk} \delta_k(A_q) = \mathbf{t}_{xq}, \quad q = 1, ..., Q,$$

where $\delta_k(A_q)$ is the indicator variable that takes value 1 if unit k is in frame q and zero otherwise, and $\mathbf{t}_{xq}$ are the population totals of $\mathbf{x_q}$.

The proposed model calibration estimator eliminates overestimation issues by several means. We consider $d_k^M(q)$ as the starting weights for the calibration and using the indicator variables $\delta_k(A_q)$, the calibration constraints ensure adjustment of the multiplicity issues by benchmarking all information on units from frame A_q included in the sample, irrespective of the frame they were originally selected from. Therefore, again, multiplicity is accounted for automatically by the constraints. The properties of this estimator can be derived from the properties of the calibrated estimators in multiple frames (see Ranalli et al. (2016))

 ISBN: 978-84-617-8694-7

7 Conclusions

In this paper, we present a new procedure aimed at determining a population sensitive mean by using a randomized response model when data are obtained from several frames. We introduce a way of combining estimates from the different frames. In practice, a different sampling procedure might feasibly be applied for each frame, or even no randomization at all (i.e., direct response) for a particular frame. The use of RR techniques has advantages but also drawbacks (the variance of estimates is increased by the randomization and individual response patterns cannot be interpreted directly, due to the observation of randomized responses, nor can individuals or groups of individuals be compared). Nevertheless, by making combined use of RR and direct answering in the sample, information that is both more valid and more reliable can be obtained.

Abstract

Nowadays, Deep Learning is one of the most popular techniques which is used in several fields like handwriting text recognition. This paper presents the first steps for our propose for a handwritten text recognition system. Our system is based in Convolutional Neural Networks and it is trained using an on-demand scheme to recognize the existing characters from the IAM dataset. We show that using these training samples, it is not necessary segment or normalize the input images. Average accuracy recognition results were 85.5% for characters and 35.1% for words, respectively. The accuracy distribution depends on the lengths of the sequences. Moreover, in more than 48.8% of wrongly predicted numbers there was only one or two character errors.

Key words: Deep Learning, Handwriting Recognition, Convolutional Neural Network.

1 Introduction

"Aoccdrnig to a rscheearch at Cmabrigde Uinervtisy, it deosn't mttaer in waht oredr the ltteers in a wrod are, the olny iprmoetnt tihng is taht the frist and lsat ltteer be at the rghit pclae. The rset can be a toatl mses and you can sitll raed it wouthit porbelm. Tihs is bcuseae the huamn mnid deos not raed ervey lteter by istlef, but the wrod as a wlohe." Or rather, "According to a researcher (sic) at Cambridge University, it doesn't matter in what order the letters in a word are, the only important thing is that the first and last letter be at the right place. The rest can be a total mess and you can still read it without problem. This is because the human mind does not read every letter by itself but the word as a whole". Although this sentence have been circulated on the Internet since 2003, there are a

 ISBN: 978-84-617-8694-7

few studies that support this idea (or at least a part of it) ([13], [14]). The goal of this paper is to build the first steps of a handwriting recognition system which reads one word as a whole and recognizes it. In this system, the order of the letters are not relevant at all as the previous sentence stated. That means that, differently from most of the handwritten text recognition systems, we will not sequence the input images into their component characters using a sliding window. The first step of or recognition system is identifying the different characters being part of a word, and this task is in what we focus our paper.

We will work with handwriting text images. This can be done with the off-line approach or with the on-line approach, where in the last case the system uses dynamic information captured while someone is writing. These two approaches are the main ones for the automatic handwriting recognition process [12]. On the other hand, reading the word as a whole corresponds to the holistic approach, while in the segmented-based approach isolated characters are extracted to perform their classification ([18], [9]).

The segmentation phase has been one of the most important stages in the recognition systems. Many techniques aim to predict isolated characters and concatenate them, instead of predicting the whole words. A good segmentation reduces the recognition errors, so that many authors have focused their research in it [9]. Most recent techniques handle the whole word without segmentation [2], but sequence modeling with a sliding window is necessary in this case. Moreover, it is a frequent practice to normalize the text images to reduce their variability in order to achieve better recognition results.

Despite of the fact that there are many improvements in these recognition systems (especially with the appearence of Deep Learning techniques), there are still several problems to be solved. The possible high length-variability of text words in senteces, and the image noise presence must also be taken into account. In particular, this length variability in words may difficult the character segmentation task, and the presence of noise can cause that the system wrongly isolates some characters. Other approaches are non segmented-based, but instead, these use a sliding window to sequence the characters. Other non segmented-based systems, as [4], [5] and [6], use different techniques like Hidden Markov Models (HMM), Neural Netwoks(NN), Hybrid NN/HMM and Convolutional Networks (CNN) as classifiers. Moreover, to our knowledege, there are not techniques which handle the image as a whole without performing segmentation or using sliding windows.

The presence of high text variability and of noise can be reduced by using normalization techniques such as skew correction, baseline extraction, slant normalization, size normalization and contour smoothing [1]. In our system, instead of normalizing the images, we apply some types of random transformations to increase the sample size as in [16]. With this method we generate a "more realistic and almost infinite sample".

On one hand, for the above referred normalization-based methods, after that step a segmentation algorithm is applied in order to get isolated characters. One of the most used ones to extract the word characters consists on splitting the words into connected

 ISBN: 978-84-617-8694-7

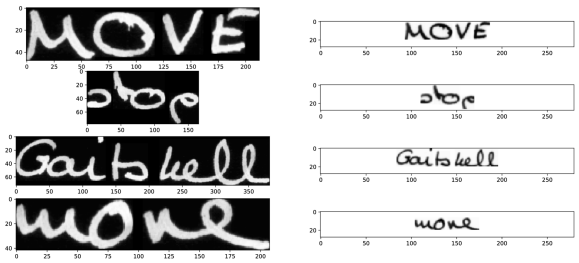

Figure 1: Examples IAM normalization

components which are classified as characters [9]. On the other hand, as our method does neither need from normalization nor segmentation, the text and noise variability conditions will be higher and this makes it more difficult the recognition task itself as it happens in many practical situations.

In this paper, we describe the first steps of a new deep learning approach for handwritten word recognition. Our method does not need from any normalization and segmentation or sliding windows stages, and it has been successfully tested on IAM dataset. The proposed system learns from an on-demand basis for generating infinite samples from IAM database, instead of using a standard fixed-length database.

The paper is organized as follows. Section 2 describes the generation of our experimental training examples from IAM dataset. Section 3 outlines the system architecture for the considered problem. Our experimental results are presented and explained in Section 4. Finally, the last Section summarizes the conclusions of this work.

2 Handwritten character database

We use IAM database to train and test our system [10]. This dataset is formed by 115,320 images, from which 97,704 are used of training and 17,616 are of tests, respectively. All of these samples are black and white images, centered and non size-normalized. For training and testing our system, we normalized the size of the images to 28×280 pixels. The relative position between characters is important to differentiate them. For example, the characters "l" and "e" sometimes just differ in their height. For that reason, we have extracted the upper and lower baselines of each word, and centered and reescaled them in order to fit to the new normalized baseline. Figure 1 shows some examples of IAM normalized images. Finally, the infinite sample was the result of moving and transforming the normalized images.

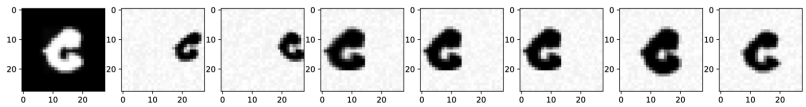

Figure 2: Example of the image transformations: (a) original image, (b) affine transformation to the right, (c) affine transformation to the left, (d), (e) and (f) respective transforamtions with increase of 15% of the heigth, width, and both, (g) dilated image, and (h) eroded one.

2.1 Transformations applied to images

In order to add more variability and get an infinite sample, some transformations are applied to the generated images. The generator can choose whether or not the following transformations are applied (see Figure 2):

1. Affine transformation to the right or to the left in order to rotate the image.
2. Increase the scale of the digfits by width or by height.
3. Morphological erosion.
4. Morphological dilation.
5. Translate the position of letters.

At the end of these transformations, a random background (with pixels between 240-255 graylevel values) is added to the image in order to avoid the noise which is produced when a transformation is applied. Note that it is possible to use more than one transformation in the same generated sequence. By the other hand, in the *Move* transformation, the sequence will be displaced to the right randomdly or using a fixed scalar.

3 Architecture proposal

The proposed model is based on the VGG architecture [17], and its goal is to predict the existing characters in an text image. This architecture is composed by stacks of convolutional layers which are followed by dense layers. The convolutional layers extract the letters features while the dense layers summarize that information to identify which characters are present in the image. Note that, as the convolution functions are invariant to rotations and translations, the positions and frequencies of the letters are not important at all. On the other hand, the target of that model is a binary vector

 ISBN: 978-84-617-8694-7

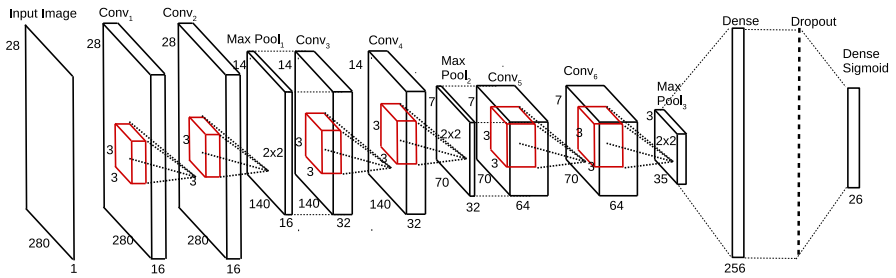

Figure 3: CNN Model Architecture.

$\mathbf{y} \in M^{26}$ where $\mathbf{y} = (y_0, \cdots y_{25})$ $/y_i = 1$ if class i is in the image. Uppercase and lowercase letters have been considered as representing the same label or class. Figure 3 shows the general model architecture of our system.

As it is shown, this architecture is composed by three blocks of convolutional layers stacked. In each stack, the kernel sizes are increased and the layers are followed by a sub-sampling (in particular, max-pooling). The last two layers are dense ones. In the first dense layer, a dropout of 60% was used as regularization method [15]. All the convolutions layers have a stride of 3×3 (which is equivalent to have a stride of 5×5 due to there are two consecutive convolution layers) and zero-padding. Also, all the neurons use ReLU [7] as activation function.

As pointed out before, we have used the real words from the IAM database to train our model. Real words are more challenging to train than isolated characters due to, in most times, there is not space between letters and some characters are deformed. Next section explains the results obtained by this recognition system.

4 Experiments

For training our model we used a Stochastic Gradient Descent (SGD) as optimizator. This type of optimizator works with batches of training examples, by decreasing the computation cost with a fast convervenge [3]. Moreover, we use a learning rate of 0.1. On the other hand, the model was trained during 500 epochs.

To measure the model goodness, we define the Character Accuracy Rate (CAR) and the Sequence Accuracy Rate (SAR), which measure how many correct predicted letters there are in all the tested words, and how many tested words have all their letters well predicted respectively:

$$CAR = \frac{\text{N}^{\text{o}} \text{ of correct test characters}}{\text{Total Number of test characters}}$$

 ISBN: 978-84-617-8694-7

	CAR	SAR
IAM examples	85.5%	35.1%

Table 1: Summary of recognition results of our system for isolated letters (CAR column) and variable-length numbers (SAR column)

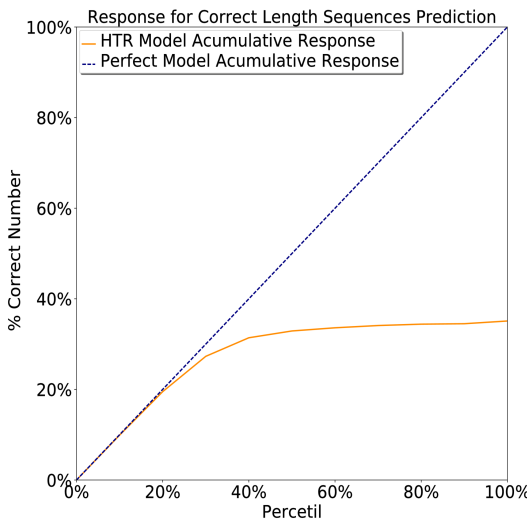

Figure 4: Accuracy rate for proposed model vs perfect model

$$SAR = \frac{\text{N}^{\text{o}} \text{ test sequence where all their characters are correct}}{\text{Total Number of test sequence}}$$

We tested these measures with 1000 test examples. As it is shown on Table 1, we have achieved an 85.5% of CAR and a 35.1% of SAR, respectively:

Figure 4 shows the accuracy rate by percentils of our model and compares it with the perfect model, i.e. when all the examples are well predicted). This graph have been built by sorting the predictions by their confidence. Note that these confidences have been calculated by summing the probabilties of each predicted letters. It is noticed that, if the 10% of the predictions with highest confidence is chosen, all of the tested examples are well predicted.

Figure 5 (a) shows the sequences length distribution for the correct predicted sequences. It's observed that there are more accuracy in words with lenght 2 or 3. Note that these lengths are the most frequent ones in the lengths distribution, as it is shown in Figure 5

 ISBN: 978-84-617-8694-7

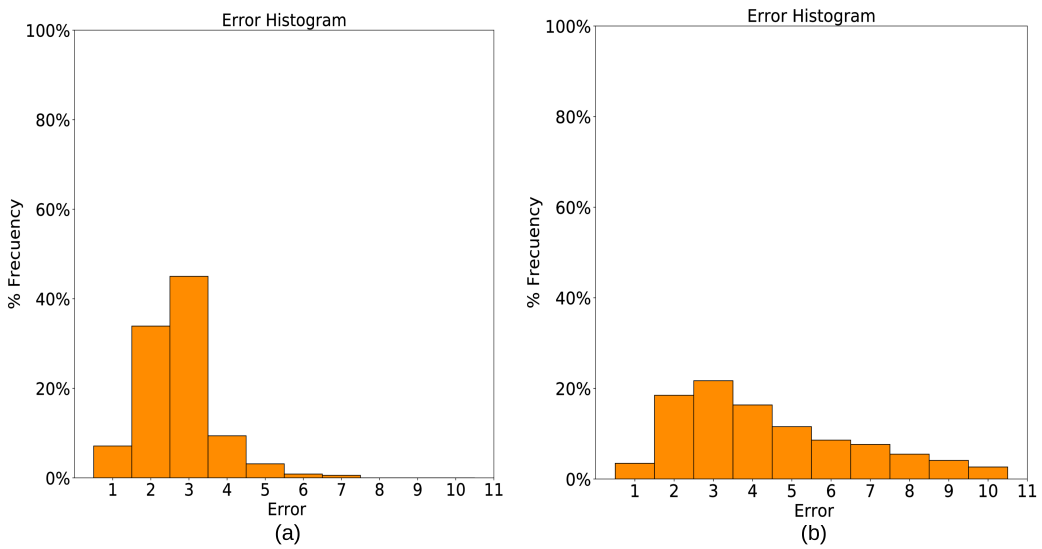

Figure 5: Recognition results: (a)frequency of well classified IAM test sequences by their number length and (b) frequency of IAM test words by their number length

(b).

Finally, we have also studied how much the system predicted wrongly by using the edit distribution [8] and the correct sequences' length distributions. Figure 6 shows that 35.1% of the tested words have 0 errors, 31.7% have 1 or 2 errors, and 33.2% have more than 2 errors. That means that the 48.8% of the wrong predictions have 1 or 2 errors.

5 Conclusions

This paper described the first stages of a new automatic system for handwriting recognition. This system aims to predict words as a whole without using neither segmentation nor sliding windows. This paper mainly focused on the task of identifying the existing letters in the handwritten word images. Our system was trained with an on-demand scheme using IAM database. As a result, we achieved a 85.5% in Character Accuracy Rate and 35.1% of Sequence Accuracy Rate. Moroever, the accuracy is higher in real words of length between 2 or 3. Finally, the 48.8% of the wrong predictions only have 1 or 2 errors. In the future, we will improve this model in order to predict complete handwritten words, and not just their component letters.

Abstract

In this short paper we show a deep learning architecture for recognizing the handwritten numbers which are presented to it, as an off-line scanned continuous digit sequence. The presented architecture is composed by a Convolutional Neural Network, a Long Short-Term Memory and a Multilayer Perceptron. The inputs to this system consist in digit sequences that have been previously generated using the MNIST database. This paper also describes the data augmentation performed for training the proposed architecture. The obtained results, which are combined with the features extracted by another Convolutional Neural Network, could be used to predict the numbers presented to the system.

Key words: Deep Learning, Handwriting Recognition, Convolutional Neural Network, Long Short-Term Memory.

1 Introduction

Off-line continuous handwritten recognition continues being an open research area. There are no commercial or free system which allows handwritten recognition with comparable accuracy to a human being. However, recent deep learning approaches are making important progresses for this task[1][3].

In the literature, we can see that there are two classical ways to recognize a word [4]. The first one consists in splitting the word in their component characters. This means that some type of segmentation process is needed. The method does not need from a dictionary, and so it can predict words that the system has not seen before. The second way consists in learning each word as a whole. In this case, the system usually needs to be trained with many examples of each possible word. Our group is working with an intermediate approach.

 ISBN: 978-84-617-8694-7

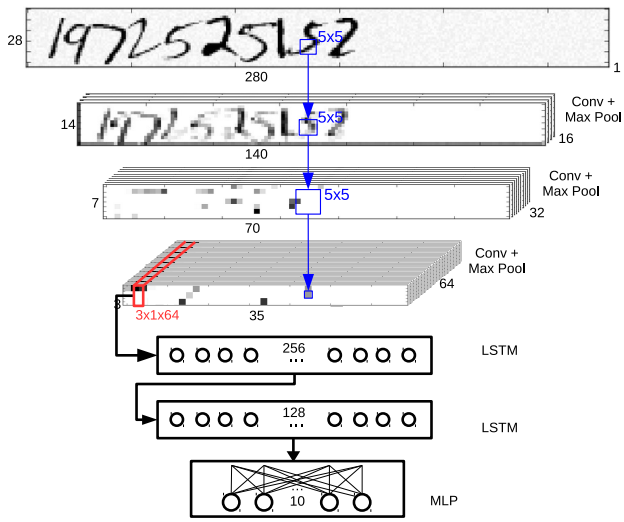

Figure 1: Proposed architecture for number recognition.

We recognize each word as a whole, but we do not need one example word of each type. That is because our recognition method is based in some features such as the components characters and the number of characters in the word. However, unlike segmentation-based systems, our proposal does not need to know exactly where a character ends and when it begins the next one.

In this short paper we present a part of our word recognition system, which is able ti determine the number of characters contained in a word. This part is based in a deep learning architecture that combines a Convolutional Neural Network (CNN), a Long Short Term Memory Network (LSTM) and a Multilayer Perceptron (MLP).

2 Architecture proposal

Our proposal consists in a CNN followed by a LSTM network and a MLP (see Figure 1). The CNN is devoted to extract the features that characterize a given digit sequence. The LSTM, whose input is the output of the last convolutional layer in the CNN, is targeted to obtain the length of the digit sequence. Finally, after the LSTM, it appears a fully-connected MLP with 10 output units corresponding to each possible digit.

 ISBN: 978-84-617-8694-7

	Number of errors		
	0	1	2
Number of cases	868	131	1
Percentage(%)	86.8	15	0.1

Table 1: Results obtained when the system predicts the length of the test digit sequences.

3 Experiments

This network is trained in two stages. In a first stage, the CNN is trained to predict the digits presented at its input. In this first stage, a MLP was concatenated to the CNN. When this network was trained, then the MLP layers were removed, and the LSTM was disposed after the CNN. Finally, a MLP was placed after the LSTM. When this architecture was completed, it was trained as a whole.

The network was trained using the MNIST handwritten digit database [2]. At each training step, a random digit sequence was generated from the training set. In addition skew and dilate transformations were applied to thos sequence in order to increase its variability.

To test our system, random digit sequences were generated from the test set. Table 1 (a) shows that the length of each sequence is predicted correctly in the 86.8% of the cases, and the error is only of one unit in the rest of the cases.

4 Conclusions

In this paper a deep learning model for length digit sequence estimation has been proposed. As future work, we propose to train this model with handwritten continuous text. Then, it will be used to decide the number of time steps of a recurrent model, trained to recognize a continuous handwritten word.

emails: lorena.saavedra@usc.es

Abstract

This paper is devoted to prove the existence of one or multiple solutions for a family of nonlinear fourth order boundary value problems.

We use several fixed point theorems, previously developed by the authors, to prove the existence of solutions of some simply supported beam problems.

To finish the work, a particular case is studied and the existence of multiple solutions is proved for two different particular nonlinear functions.

Key words: Green's functions, fixed point theorems, nonlinear boundary value problems

MSC 2000: 34B15, 34B27, 34B18, 47H10

1 Introduction

The aim of this paper is to ensure the existence of one or multiple positive solutions for the fourth order problem:

$$\begin{cases} T_4[M]\,u(t) = f(t,u(t))\,, & t \in I \equiv [a,b]\,, \\ u(a) = u''(a) = u(b) = u''(b) = 0\,, \end{cases} \tag{1}$$

where $T_4[M]\,u(t) = u^{(4)}(t) + p_1(t)\,u^{(3)}(t) + p_2(t)\,u''(t) + M\,u(t)$, $p_1 \in C^3(I)$ and $p_2 \in C^2(I)$.

The simply supported beam problem (1) has been widely developed in the literature. For instance, in [2, 6, 7, 8], it is studied the existence of unique constant sign solutions of the following linear problem

$$\begin{cases} u^{(4)}(t) + c(t)\,u(t) = f(t)\,, & t \in [0,1]\,, \\ u(0) = u''(0) = u(1) = u''(1) = 0\,, \end{cases}$$

 ISBN: 978-84-617-8694-7

where $c,\ f \in C([0,1])$.

In [5], there are proved some results which ensure the existence of one or multiple solutions for a n^{th}-order nonlinear differential equation coupled with the so-called $(k, n-k)$ boundary conditions, which are defined by:

$$u(a) = u'(a) = \cdots = u^{(k-1)}(a) = 0\,, \quad u(b) = u'(b) = \cdots = u^{(n-k-1)}(b) = 0\,.$$

This existence of solution needs as hypothesis that the related Green's function, $g_M(t,s)$, satisfies the following suitable property:

(Pg_1) There exist Φ, k_1 and k_2 continuous functions on I such that $\Phi(s) > 0$ for all $s \in (a,b)$, $0 < k_1(t) \leqslant k_2(t)$ for all $t \in (a,b)$ and

$$\Phi(s)\, k_1(t) \leqslant g_M(t,s) \leqslant \Phi(s)\, k_2(t)\,, \quad \forall (t,s) \in I \times I\,.$$

From the constant sign Green's function characterization related to the operator $T_4[M]$, previously defined, in the set

$$X = \left\{ u \in C^4(I) \ \mid \ u(a) = u''(a) = u(b) = u''(b) \right\}, \tag{2}$$

obtained in [4] by means of spectral theory, it can be characterized the parameter set for which the related Green's function of $T_4[M]$ in X verifies either the property (Pg_1) or the analogous for the negative case:

(Ng_1) There exist Φ, k_1 and k_2 continuous functions on I such that $\Phi(s) > 0$ for all $s \in (a,b)$, $0 > k_1(t) \geqslant k_2(t)$ for all $t \in (a,b)$ and

$$\Phi(s)\, k_1(t) \geqslant g_M(t,s) \geqslant \Phi(s)\, k_2(t)\,, \quad \forall (t,s) \in I \times I\,.$$

Remark 1.1. *It is clear that if the Green's function related to problem* (1) *satisfies the property* (Ng_1)*, then the related Green's function to problem*

$$\begin{cases} T_4[M]\, u(t) + f(t, u(t)) = 0\,, & t \in I \equiv [a,b]\,, \\ u(a) = u''(a) = u(b) = u''(b) = 0\,, \end{cases}$$

satisfies the property (Pg_1)*, just by taking* $\tilde{k}_1(t) = -k_2(t)$ *and* $\tilde{k}_2(t) = -k_1(t)$.

Thus, in order to obtain the existence results from the ones proved in [5], we need to impose conditions on $-f(t,u)$ *instead of* $f(t,u)$.

In a preliminary section we transform our problem into a fixed point problem. Then, we show the results collected in [5] which ensure the existence of one or multiple fixed points under suitable hypotheses. To finish this section, it is characterized the parameter set for which the related function of problem (1) satisfies either the property (Pg_1) or (Ng_1).

In the main section of this paper, it is proved the existence of solution for a particular simply supported beam problem by applying the previous results.

 ISBN: 978-84-617-8694-7

2 Fixed point formulation and preliminary results

First, let us denote $g_M(t,s)$, as the related Green's function of problem (1).

It is well-known that the solutions of (1) are determined by the fixed points of the following integral operator:

$$\mathcal{L}[M]\,u(t) = \int_a^b g_M(t,s)\,f(s,u(s))\,ds\,. \tag{3}$$

Let us consider the Banach space $\mathcal{B} = C(I)$ coupled with the norm:

$$\|u\|_\infty = \max_{t\in I} |u(t)|\,.$$

Let us assume that $g_M(t,s)$ satisfies the property (Pg_1). Consider the subinterval $I_1 = [a_1, b_1] \subset I$, such that $k_1(t) > 0$ for all $t \in I_1$ and we denote:

$$K_1 = \|k_1\|_\infty\,, \quad K_2 = \|k_2\|_\infty \ \text{ and } \ m_1 = \min_{t\in I_1} k_1(t)\,. \tag{4}$$

In the sequel, we enunciate the results, collected in [5], where some sufficient conditions to ensure the existence of one or multiple fixed points of $\mathcal{L}$ are shown.

Let us consider the following conditions on f:

(H_1) $\exists\, p > 0$ such that $f(t,u) \leqslant \dfrac{p}{K_2 \int_a^b \Phi(s)\,ds}\,, \quad \forall\, t \in I\,,\ \forall\, u \in [0,p]\,.$

(H_2) $\exists\, q > 0$ such that $f(t,u) \geqslant \dfrac{K_2\, u}{K_1 \int_{a_1}^{b_1} k_1(s)\,\Phi(s)\,ds}\,, \quad \forall\, t \in I_1\,,\ \forall\, u \in \left[\frac{m_1}{K_2}\,q, q\right].$

Then, we have the following result.

Theorem 2.1. *Suppose that there exist two positive numbers $p \neq q$ such that condition (H_1) is satisfied with respect to p and condition (H_2) is satisfied with respect to q. Then, provided that the integral kernel g_M satisfies (Pg_1), operator $\mathcal{L}$, defined in (3), has a fixed point, $u \in \mathcal{B}$, such that $\|u\|_\infty$ lies between p and q.*

Now, for the existence of at least two fixed points, we have the next theorem.

Theorem 2.2. *Suppose that there exist positive numbers p, q and r such that $0 < p < q < r$, and assume that function f satisfies the following conditions:*

(i) $f(t,u) \geqslant \dfrac{u}{m_1 \int_{a_1}^{b_1} \Phi(s)\,ds}\ \forall\, t \in I_1$ *and* $u \in \left[r, \frac{K_2}{m_1}\,r\right]$, *being the inequality strict at* $u = r$,

(ii) $f(t,u) \leqslant \dfrac{q}{K_2 \int_a^b \Phi(s)\,ds}\ \forall\, t \in I$ *and* $u \in \left[0, \frac{K_2}{m_1}\,q\right]$, *being the inequality strict at* $u = q$,

 ISBN: 978-84-617-8694-7

(*iii*) $f(t,u) > \dfrac{K_2\, u}{K_1 \int_{a_1}^{b_1} k_1(s)\, \Phi(s)\, ds}$ *for all* $t \in I_1$ *and* $u \in \left[\dfrac{m_1}{K_2}\, p, p\right]$.

Then, if g_M *satisfies* (Pg_1)*, the operator* $\mathcal{L}$ *has at least two fixed points,* u_1 *and* u_2*, such that* $p < \|u_1\|_\infty\,, \quad \max_{t\in I_1} u_1(t) < q < \max_{t\in I_1} u_2(t)\,, \quad \min_{t\in I_1} u_2(t) < r\,.$

Finally, we have the next result which ensures the existence of, at least, three fixed points.

Theorem 2.3. *Let* p*,* q *and* r *be positive numbers satisfying* $0 < p < q < \dfrac{K_2}{m_1} q \leqslant r\,.$

Assume, moreover, that the function f *satisfies the following conditions:*

(*a*) $f(t,u) \leqslant \dfrac{r}{K_2 \int_a^b \Phi(s)\, ds}$ *for all* $t \in I$ *and* $u \in [0,r]$,

(*b*) $f(t,u) < \dfrac{p}{K_2 \int_a^b \Phi(s)\, ds}$ *for all* $t \in I$ *and* $u \in [0,p]$,

(*c*) $f(t,u) \geqslant \dfrac{u}{m_1 \int_{a_1}^{b_1} \Phi(s)\, ds}$ $\forall\, t \in I_1$ *and* $u \in \left[q, \frac{K_2}{m_1} q\right]$*, being the inequality strict for* $u = q$.

Then, if g_M *satisfies* (Pg_1)*, the operator* $\mathcal{L}$ *has at least three fixed points* u_1*,* u_2*,* u_3 *such that* $\|u_i\|_\infty \leqslant r$ *for* $i = 1,2,3$ *and* $\max_{t\in I_1} u_1(t) < p < \min_{t\in I_1} u_2(t)\,,\ \max_{t\in I_1} u_2(t) < q < \min_{t\in I_1} u_3(t)\,.$

Now, following the characterization of the constant sign Green's function for problem (1), given in [4], we obtain a characterization of the parameter set where g_M satisfies either the condition (Pg_1) or (Ng_1).

First, we need to introduce a concept about the maximum number of zeros for the related second order linear differential equation:

$$u''(t) + p_1(t)\, u'(t) + p_2(t)\, u(t) = 0\,, \quad t \in I\,, \tag{5}$$

collected in [3].

Definition 2.4. *The second order linear differential equation* (5) *is said to be disconjugate on* I *if every non trivial solution has, at most, a simple zero on* I.

Remark 2.5. *The second order equation* $u''(t) = 0\,,$ *is disconjugate on every real interval,* I.

Now, we have the following result.

Theorem 2.6. *If the second order linear differential equation* (5) *is disconjugate on* I*, then the following properties are fulfilled:*

 ISBN: 978-84-617-8694-7

- *$g_M(t,s)$, the related Green's function of problem* (1)*, satisfies condition* (Pg_1) *if, and only if,* $M \in (-\lambda_1, -\lambda_2]$*, where*

  - $\lambda_3 > 0$ *is the minimum between:*
    - $\lambda_3' > 0$*, the least positive eigenvalue of* $T_4[0]$ *in*
    $$U_1 = \{u \in C^4(I) \ \mid \ u(a) = u''(a) = u(b) = u'(b) = 0\}\,.$$
    - $\lambda_3'' > 0$*, the least positive eigenvalue of* $T_4[0]$ *in*
    $$U_2 = \{u \in C^4(I) \ \mid \ u(a) = u'(a) = u(b) = u''(b) = 0\}\,.$$

Proof. From the proof of [4, Theorem 6.1], the following inequalities are fulfilled for $M \in (-\lambda_1, -\lambda_2]$.

$$\begin{aligned}
&(+\infty >) \qquad g_M(t,s) > 0\,, \quad \forall\,(t,s) \in (a,b)\times(a,b)\,,\\
&(+\infty >)\ \frac{\partial g_M(t,s)}{\partial t}_{|t=a} > 0\,, \quad \forall\, s \in (a,b)\,,\\
&(+\infty >)\ \frac{\partial g_M(t,s)}{\partial s}_{|s=a} > 0\,, \quad \forall\, t \in (a,b)\,,\\
&(-\infty <)\ \frac{\partial g_M(t,s)}{\partial t}_{|t=b} < 0\,, \quad \forall\, s \in (a,b)\,,\\
&(-\infty <)\ \frac{\partial g_M(t,s)}{\partial s}_{|s=b} < 0\,, \quad \forall\, t \in (a,b)\,.
\end{aligned}$$

Consider

$$\Phi(s) = s\,(1-s) > 0\,, \quad \forall\, s \in (a,b)\,, \tag{6}$$

and we have that

$$u(t,s) = \frac{g_M(t,s)}{\Phi(s)} > 0\,, \quad \forall\,(t,s) \in (a,b)\times(a,b)\,.$$

 ISBN: 978-84-617-8694-7

Moreover, we obtain the following real limits:

$$\lim_{s\to a^+}\frac{g_M(t,s)}{\Phi(s)}=\frac{\frac{\partial g_M(t,s)}{\partial s}_{|s=a}}{b-a}>0\,,\quad\forall\,t\in(a,b)\,,$$
$$\lim_{s\to b^-}\frac{g_M(t,s)}{\Phi(s)}=\frac{\frac{\partial g_M(t,s)}{\partial s}_{|s=b}}{-(b-a)}>0\,,\quad\forall\,t\in(a,b)\,.$$

So, we define $\tilde{u}(t,s)$, as the continuous extension of $u(t,s)$ to $(a,b)\times I$, and taking

$$\begin{aligned}k_1(t)&:=\min_{s\in I}\tilde{u}(t,s)>0\,,\quad\forall\,t\in(a,b)\,,\\ k_2(t)&:=\max_{s\in I}\tilde{u}(t,s)>0\,,\quad\forall\,t\in(a,b)\,,\end{aligned}\tag{7}$$

clearly, property (Pg_1) is fulfilled by g_M if $M\in(-\lambda_1,-\lambda_2]$.

On the other hand, from the proof of [4, Theorem 6.1], it is deduced that if $M\in[-\lambda_3,-\lambda_1)$, then:

$$\begin{aligned}(-\infty<)\qquad g_M(t,s)&<0\,,\quad\forall\,(t,s)\in(a,b)\times(a,b)\,,\\ (-\infty<)\,\frac{\partial g_M(t,s)}{\partial t}_{|t=a}&<0\,,\quad\forall\,s\in(a,b)\,,\\ (-\infty<)\,\frac{\partial g_M(t,s)}{\partial s}_{|s=a}&<0\,,\quad\forall\,t\in(a,b)\,,\\ (+\infty>)\,\frac{\partial g_M(t,s)}{\partial t}_{|t=b}&>0\,,\quad\forall\,s\in(a,b)\,,\\ (+\infty>)\,\frac{\partial g_M(t,s)}{\partial s}_{|s=b}&>0\,,\quad\forall\,t\in(a,b)\,.\end{aligned}$$

Thus, proceeding as in the positive case, we obtain that (Ng_1) is fulfilled by taking $\Phi(s)$ defined in (6) and

$$\begin{aligned}k_1(t)&:=\max_{s\in I}\tilde{u}(t,s)<0\,,\quad\forall\,t\in(a,b)\,,\\ k_2(t)&:=\min_{s\in I}\tilde{u}(t,s)<0\,,\quad\forall\,t\in(a,b)\,,\end{aligned}$$

Finally, in [4, Theorem 6.1], it is proved that if $M\notin[-\lambda_3,-\lambda_2]$, then $g_M(t,s)$ oscillates on the square $I\times I$. Thus, neither property (Pg_1) or (Ng_1) can be fulfilled. □

Remark 2.7. *Realize that from Theorems 2.1, 2.2 and 2.3, we prove the existence of non-negative solutions for problem* (1)*, under the hypothesis that $g_M(t,s)$ satisfies property (Pg_1).*

Proceeding analogously, by imposing property (Ng_1) on $g_M(t,s)$ instead of (Pg_1), we can prove the existence of non-positive solutions for problem (1) *by repeating the arguments done in [5], with the same assumptions on f, choosing $m_1=-\max_{t\in I_1}k_1(t)$ and K_1, K_2 as in* (4).

 ISBN: 978-84-617-8694-7

3 Existence results for particular simply supported beam problems

From Remark 2.5, Theorem 2.6 can be applied to the fourth order operator

$$T_4^0[M]\,u(t) = u^{(4)}(t) + M\,u(t)\,, \quad t \in I\,. \tag{8}$$

Let us choose $I = [0,1]$, and, in [4], there are obtained the different eigenvalues of operator $T_4^0[0] = \frac{d^4}{dt^4}$.

- $\lambda_1 = \pi^4$ is the least positive eigenvalue of $T_4^0[0]$ in X.
- $\lambda_2 = -m_1^4 \approxeq -5.55^4$, where m_1 is the least positive solution of $\tan\left(\frac{m}{\sqrt{2}}\right) = \tanh\left(\frac{m}{\sqrt{2}}\right)$, is the biggest negative eigenvalue of $T_4^0[0]$ in X_1 and X_3.
- $\lambda_3 = m_2^4 \approxeq 3.927^4$, with m_2 the least positive solution of $\tan(m) = \tanh(m)$, is the least positive eigenvalue of $T_4^0[0]$ in U_1 and U_2.

So, if we denote $g_M^0(t,s)$ as the related Green's function of problem (1), where $T_4[M] = T_4^0[M]$, from Theorem 2.6, we can conclude:

- $g_M^0(t,s)$ satisfies property (Pg_1) if, and only if, M belongs to the interval $(-\pi^4, 5.55^4]$.
- $g_M^0(t,s)$ satisfies property (Ng_1) if, and only if, M is in the interval $[-3.927, -\pi^4)$.

Remark 3.1. *For $M \in (-\lambda_1, -\lambda_2] \approxeq (-\pi^4, 5.55^4]$, since the property (Pg_1) is fulfilled by the related Greens function, we are able to obtain the continuous functions k_1 and k_2 associated to the problem*

$$\begin{cases} u^{(4)}(t) + M\,u(t) = f(t,u(t))\,, & t \in [0,1]\,, \\ u(0) = u''(0) = u(1) = u''(1) = 0\,. \end{cases}$$

The construction of these functions is described on the proof of Theorem 2.6. The difficulty remains in the expression of the related Green's function.

Sometimes, it is really difficult to find the exact functions k_1 and k_2 as they are defined in (7). However, we can consider some approximations, ℓ_1 and ℓ_2, such that $\ell_1(t) \leqslant k_1(t)$ and $\ell_2(t) \geqslant k_2(t)\,, \quad \forall\, t \in [0,1]\,.$

Clearly, the bounds obtained with ℓ_1 and ℓ_2 are still valid for Theorems 2.1, 2.2 and 2.3.

Remark 3.2. *Once that property (Pg_1) is proved, as a consequence of Theorem 2.1 the existence of at least one positive solution for problem (1), with $T_4[M] = T_4^0[M]$, can be proved*

 ISBN: 978-84-617-8694-7

if f is either sub-linear $\left(\lim_{u\to 0^+}\dfrac{f(t,u)}{u}=+\infty \text{ and } \lim_{u\to+\infty}\dfrac{f(t,u)}{u}=0\right)$ *or super-linear* $\left(\lim_{u\to 0^+}\dfrac{f(t,u)}{u}=0 \text{ and } \lim_{u\to+\infty}\dfrac{f(t,u)}{u}=+\infty\right)$ *without obtaining k_1 and k_2.*

Remark 3.3. *Using Remarks 1.1 and 2.7, from property (Ng_1) similar conclusions than those in the previous remarks can be obtained for $M\in[-\lambda_3,-\lambda_1)\approxeq[-3.927^4,-\pi^4)$.*

In the sequel we will obtain the different bounds and results for the particular case when $M=0$.

That is, we want to prove the existence of one or multiple positive solutions of the problem:

$$\begin{cases} u^{(4)}(t)=f(t,u(t)), & t\in[0,1], \\ u(0)=u''(0)=u(1)=u''(1)=0. \end{cases} \tag{9}$$

Φ is given in (6). Now, let us obtain the correspondent k_1 and k_2.

We have to calculate the related Green's function. By means of the Mathematica program developed in [1], we obtain:

$$g_0^0(t,s)=\begin{cases} \frac{1}{6}\,s\,(1-t)\left((2-t)\,t-s^2\right), & 0\leqslant s\leqslant t\leqslant 1, \\ \\ \frac{1}{6}\,t\,(1-s)\left((2-s)\,s-t^2\right), & 0<t<s\leqslant 1. \end{cases}$$

Thus, clearly, for this case

$$\tilde{u}(t,s)=\begin{cases} \frac{1}{6}\cdot\frac{1-t}{1-s}\left((2-t)\,t-s^2\right), & 0\leqslant s\leqslant t<1,\ t\neq 0 \\ \\ \frac{1}{6}\cdot\frac{t}{s}\left((2-s)\,s-t^2\right), & 0<t<s\leqslant 1. \end{cases}$$

So, we have

$$\frac{\partial\tilde{u}(t,s)}{\partial s}=\begin{cases} \frac{1-t}{6}\cdot\frac{(s-t)\,(s+t-2)}{(1-s)^2}, & 0\leqslant s\leqslant t<1,\ t\neq 0 \\ \\ \frac{t}{6}\cdot\frac{(t-s)\,(t+s)}{s^2}, & 0<t<s\leqslant 1. \end{cases}$$

Hence, for $s\in[0,t]$, $\tilde{u}(t,s)$ is non-decreasing as a function of s and, for $s\in[t,1]$, $\tilde{u}(t,s)$ is non-increasing as a function of s.

Therefore, we obtain $k_2(t)=\tilde{u}(t,t)=\dfrac{t\,(1-t)}{6}$, for every $t\in[0,1]$ and, we have, $k_1(t)=\min\{\tilde{u}(t,0),\tilde{u}(t,1)\}=\min\left\{\dfrac{1}{6}\,t\,(1-t)\,(2-t),\ \dfrac{1}{6}\,t\,(1-t^2)\right\}$, or, which is the same,

$$k_1(t)=\begin{cases} \frac{1}{6}\,t\,(1-t^2), & 0\leqslant t\leqslant\frac{1}{2}, \\ \\ \frac{1}{6}\,t\,(1-t)\,(2-t), & \frac{1}{2}<t\leqslant 1. \end{cases}$$

 ISBN: 978-84-617-8694-7

Directly, we obtain

$$K_1 = \|k_1\|_\infty = k_1\left(\frac{1}{2}\right) = \frac{1}{16} \quad \text{and} \quad K_2 = \|k_2\|_\infty = k_2\left(\frac{1}{2}\right) = \frac{1}{12}\,.$$

Moreover, since k_1 is a symmetric function with respect to $t = \dfrac{1}{2}$, we can choose

$$I_1 = [a_1, b_1] = \left[\frac{1}{2} - c, \frac{1}{2} + c\right], \quad c \in \left(0, \frac{1}{2}\right).$$

Clearly, $m_1 = k_1\left(\frac{1}{2} - c\right) = \frac{1}{48}\,\left(1 - 4c^2\right)\,(3 - 2c)\,.$

Now, let us obtain the bounds which appear in Theorems 2.1, 2.2 and 2.3, for the different values of $c \in \left(0, \frac{1}{2}\right)$.

Φ is defined in (6), so

$$\int_0^1 \Phi(s)\,ds = \frac{1}{6}, \quad \int_{\frac{1}{2}-c}^{\frac{1}{2}+c} \Phi(s)\,ds = \frac{1}{6}\,c\,\left(3 - 4\,c^2\right)\,,$$

and,

$$\int_{\frac{1}{2}-c}^{\frac{1}{2}+c} k_1(s)\,\Phi(s)\,ds = \frac{c\,(45 - 15\,c - 120\,c^2 + 60\,c^3 + 144\,c^4 - 80\,c^5)}{1444}\,.$$

Thus, we obtain:

$$\frac{p}{K_2\,\int_0^1 \Phi(s)\,ds} = 72\,p\,, \tag{10}$$

$$\frac{K_2\,u}{K_1\,\int_{\frac{1}{2}-c}^{\frac{1}{2}+c} k_1(s)\,\Phi(s)\,ds} = \frac{1083\,u}{c\,(45 - 15\,c - 120\,c^2 + 60\,c^3 + 144\,c^4 - 80\,c^5)}\,, \tag{11}$$

$$\frac{u}{m_1\,\int_{\frac{1}{2}-c}^{\frac{1}{2}+c} \Phi(s)\,ds} = \frac{288\,u}{c\,(3 - 4\,c^2)\,(3 - 2\,c)\,(1 - 4\,c^2)}\,. \tag{12}$$

Studying the behavior of (11) and (12) for $c \in \left(0, \frac{1}{2}\right)$, it can be easily seen that (11) is decreasing with c and (12) attains its minimum on the interval $\left[\frac{1}{5}, \frac{3}{10}\right]$.

We want to make this bounds the least possible, but we cannot minimize them together. We choose $c = \frac{3}{10}$, then $I_1 = \left[\frac{1}{5}, \frac{4}{5}\right]$ and we obtain the bounds (11) and (12) for this particular case:

$$\frac{K_2\,u}{K_1\,\int_{\frac{1}{5}}^{\frac{4}{5}} k_1(s)\,\Phi(s)\,ds} = \frac{1600000\,u}{8073}\,, \tag{13}$$

$$\frac{u}{m_1\,\int_{\frac{1}{5}}^{\frac{4}{5}} \Phi(s)\,ds} = \frac{15625\,u}{66}\,. \tag{14}$$

Thus, we can rewrite (H_1) and (H_2) for this case as follows.

 ISBN: 978-84-617-8694-7

(H_1) $\exists\, p>0$ such that $f(t,u)\leqslant 72\,p\,,\quad \forall\, t\in[0,1]\,,\ \forall\, u\in[0,p]\,.$

(H_2) $\exists\, q>0$ such that $f(t,u)\geqslant \dfrac{1600000\,u}{8073}\,,\quad \forall\, t\in\left[\frac{1}{5},\frac{4}{5}\right]\,,\ \forall\, u\in\left[\frac{48}{125}\,q,q\right].$

Using (10), (13) and (14), we rewrite Theorem 2.2 for this case.

Theorem 3.4. *Suppose that there exist positive numbers p, q and r such that $0<p<q<r$, and assume that function f satisfies the following conditions:*

(i) $f(t,u)\geqslant \dfrac{15625\,u}{66}$ $\forall\, t\in\left[\frac{1}{5},\frac{4}{5}\right]$ *and* $u\in\left[r,\frac{125}{48}\,r\right]$, *being the inequality strict at* $u=r$,

(ii) $f(t,u)\leqslant 72\,q$ $\forall\, t\in[0,1]$ *and* $u\in\left[0,\frac{125}{48}\,q\right]$, *being the inequality strict at* $u=q$,

(iii) $f(t,u)>\dfrac{1600000\,u}{8073}$ $\forall\, t\in\left[\frac{1}{5},\frac{4}{5}\right]$ *and* $u\in\left[\frac{48}{125}\,p,p\right]$.

Then, the problem (9) *has at least two positive solution, u_1 and u_2, such that*

$$p<\|u_1\|_\infty\,,\quad \max_{t\in I_1}u_1(t)<q<\max_{t\in I_1}u_2(t)\,,\quad \min_{t\in I_1}u_2(t)<r\,.$$

Now, consider the following continuous function

$$f(t,u)=\begin{cases}\dfrac{11390625}{512}\,t\,(1-t)\,u\,, & u\in\left[0,\frac{8}{225}\right],\\[2ex] \dfrac{t\,(1-t)}{u^2}\,, & u\in\left(\frac{8}{225},4\right),\\[2ex] t\,(1-t)\left(\dfrac{56607479}{15250000}u^3-\dfrac{3621925531}{244000000}u^2\right), & u\geqslant 4\,.\end{cases}\tag{15}$$

Let us choose $p=\dfrac{5}{54}$, $q=3$ and $r=\dfrac{111}{5}$. So, we have:

(i) For $u\leqslant r$, $f(t,u)\geqslant \dfrac{5\,f\left(\frac{1}{5},\frac{111}{5}\right)\,u}{111}=\dfrac{9149203310439\,u}{38125000000}\geqslant\dfrac{15625\,u}{66}$ for all $t\in\left[\dfrac{1}{5},\dfrac{4}{5}\right]$,

(ii)

$$\begin{aligned}f(t,u)&\leqslant \max\left\{\max_{t\in[0,1]}f\left(t,\frac{8}{225}\right),\max_{t\in[0,1]}f\left(t,\frac{125}{16}\right)\right\}=\max\left\{\frac{50625}{256},216\right\}\\&=216=3\cdot 72\,,\end{aligned}$$

for all $t\in[0,1]$ and $u\in\left[0,\dfrac{125}{16}\right]$, being the inequality strict for $u<\frac{125}{16}$. In particular, for $u=3$.

 ISBN: 978-84-617-8694-7

(iii) $f(t,u) = \dfrac{t\,(1-t)}{u^3}u \geqslant \dfrac{4}{25}\cdot\dfrac{157464}{125}\,u > \dfrac{1600000\,u}{8073}$ for all $t \in \left[\dfrac{1}{5},\dfrac{4}{5}\right]$ and $u \in \left[\dfrac{8}{225},\dfrac{5}{54}\right]$.

So, we can ensure the existence of at least two positive solutions for problem (9) with f defined in (15).

Finally, we have the next result which warrants the existence of three solutions by using (10) and (14).

Theorem 3.5. *Let p, q and r be positive numbers satisfying the relation:*

$$0 < p < q < \frac{125}{48}q \leqslant r\,.$$

Assume, moreover, that the function f satisfies the following conditions:

(a) $f(t,u) \leqslant 72\,r$ *for all* $t \in [0,1]$ *and* $u \in [0,r]$,

(b) $f(t,u) < 72\,p$ *for all* $t \in [0,1]$ *and* $u \in [0,p]$,

(c) $f(t,u) \geqslant \dfrac{15625\,u}{66}$ $\forall\, t \in \left[\frac{1}{5},\frac{4}{5}\right]$ *and* $u \in \left[q,\frac{125}{48}q\right]$, *being the inequality strict for* $u = q$.

Then, the problem (9) *has at least three solutions,* u_1, u_2, u_3 *such that* $\|u_i\|_\infty \leqslant r$ *for* $i = 1,2,3$ *and*

$$\max_{t\in I_1} u_1(t) < p < \max_{t\in I_1} u_2(t)\,, \quad \min_{t\in I_1} u_2(t) < q < \min_{t\in I_1} u_3(t)\,.$$

Consider the continuous function:

$$f(t,u) = \begin{cases} 1400\,t\,(1-t)\,u^2, & u \geqslant \frac{7}{2}\,, \\ \\ 17150\,t\,(1-t)\,, & u > \frac{7}{2}\,. \end{cases} \tag{16}$$

Let us choose $r = 60$, $p = \frac{1}{5}$ and $q = \frac{5}{4}$, we have:

(a) $f(t,u) \leqslant \dfrac{17150}{4} < 60\cdot 72$ for all $t \in [0,1]$ and $u \in [0,60]$,

(b) $f(t,u) \leqslant \dfrac{1400}{4}\cdot\dfrac{1}{5^2} = 14 < 72\cdot\dfrac{1}{5}$ for all $t \in [0,1]$ and $u \in \left[0,\frac{1}{5}\right]$,

(c) $f(t,u) \geqslant \dfrac{1400\cdot 4}{5^2}\cdot\dfrac{5}{4}\,u = 280\,u > \dfrac{15625\,u}{66}$ for all $t \in \left[\dfrac{1}{5},\dfrac{4}{5}\right]$ and $u \in \left[\dfrac{5}{4},\dfrac{625}{192}\right]$.

Thus, by using the previous result, we conclude that problem (9) has at least three solutions for f defined in (16).

Note on resonant problems

Felix Sadyrbaev[1]

emails: felix@latnet.lv

Abstract

The second order boundary value problem with the Dirichlet boundary conditions is essentially resonant if it has k-resonant solution.

Key words: resonant boundary value problem
MSC 2000: 34B15

1 Introduction

The second order boundary value problem (BVP in short)

$$x'' + p(t)x' + q(t)x = \varphi(t, x, x'), \tag{1}$$

$$x(a) = A, \quad x(b) = B, \tag{2}$$

where all coefficients and functions are continuous and the right side φ is bounded (in modulus) is solvable if the homogeneous problem

$$x'' + p(t)x' + q(t)x = 0, \tag{3}$$

$$x(a) = 0, \quad x(b) = 0 \tag{4}$$

has only the trivial solution ([1]). If φ is not bounded various approaches and techniques can be used to reduce the problem to the quasi-linear form with bounded right hand side.

In case the homogeneous problem (3), (4) has a nontrivial solution the problem (1), (2) is called *resonant*. Resonant problems may have no solutions even for the simple case $\varphi = \varphi(t)$. The Fredholm alternative provides criteria for solvability in this case.

In this note we wish to emphasize that formally resonant problems mostly are not essentially resonant.

 ISBN: 978-84-617-8694-7

2 Definitions

To make this idea more precise we will move to the final statement in several easy steps.

First, let us distinguish between linear expressions of the form $(l_2x)(t) := x'' + p(t)x' + q(t)x$. We will say that *the type of* $(l_2x)(t)$ *is* k if a solution $x(t)$ of the respective Cauchy problem

$$x'' + p(t)x' + q(t)x = 0, \quad x(a) = 0, \quad x'(a) = 1 \tag{5}$$

has exactly k zeros in the interval (a, b) and $x(b) \neq 0$.

If $x(b) = 0$ we will call the linear expression $(l_2x)(t)$ by $(k+1)$-resonant (the $x(t)$ in (5) has k internal zeros and additional zero at $t = b$).

In a similar way we classify possible solutions of the problem (1), (2). We will say that a solution $\xi(t)$ of the problem (1), (2) is of type n if the respective linear differential expression

$$y'' + p(t)y' + y(t)x - \varphi_x(t, \xi(t), \xi'(t))y - \varphi_{x'}(t, \xi(t), \xi'(t))y' \tag{6}$$

is of type n. The latter means that a solution of the Cauchy problem

$$y'' + p(t)y' + y(t)x = \varphi_x(t, \xi(t), \xi'(t))y + \varphi_{x'}(t, \xi(t), \xi'(t))y', \tag{7}$$

$$y(a) = 0, \quad y'(a) = 1 \tag{8}$$

has exactly n zeros in (a, b) and $y(b) \neq 0$. If $y(b) = 0$ we will say that $\xi(t)$ *is* $(n+1)$*-resonant solution.*

We wish to show that essentially resonant BVP is a problem that has i-resonant solution for some i.

All other "resonant" problems can be reduced to a quasi-linear form (1), (2) with a bounded right side.

Remark. It was shown in [2] that a quasi-linear problem in the form (1), (2) with linear part (in the left hand side) of the type k has a solution $x(t)$ that is either of type k, or k-resonant, or $(k + 1)$-resonant.

3 Observations

Proposition 3.1 *Suppose a resonant problem (1), (2), where φ is continuous in all arguments and continuously differentiable with respect to x and x', has a solution $\xi(t)$ of type n. Then the problem (1), (2) can be reformulated in a quasi-linear form*

$$x'' + P(t)x' + Q(t)x = \tilde{\varphi}(t, x, x'), \quad x(a) = A, \quad x(b) = B, \tag{9}$$

where the linear part $(L_2x)(t) := x'' + P(t)x' + Q(t)x$ is of type n.

ISBN: 978-84-617-8694-7

Proof. Consider $x'' + p(t)x' + q(t)x = \varphi(t, x, x')$ and $\xi''(t) + p(t)\xi'(t) + q(t)\xi(t) = \varphi(t, \xi(t), \xi'(t))$, where $\xi(t)$ is a solution of type n of the problem (1), (2). Then

$$\begin{aligned}(x-\xi)'' + p(t)(x-\xi)' \quad &+q(t)(x-\xi(t)) = \varphi(t,x,x') - \varphi(t,\xi,\xi') \\ &= \varphi_x(t,\xi,\xi')(x-\xi) + \varphi_{x'}(t,\xi,\xi')(x-\xi)' + r(t,x,x')\end{aligned} \tag{10}$$

or

$$\begin{aligned}x'' + p(t)x \quad &+q(t)x - \varphi_x x - \varphi_{x'}x' \\ &= \xi'' + p(t)\xi' + q(t)x - \varphi_x\xi - \varphi_{x'}\xi' + r(t,x,x')\end{aligned} \tag{11}$$

or, finally,

$$(L_2x)(t) = h(t) + \tilde{r}(t, x, x'),$$

where
$(L_2x)(t) = x'' + (p(t) - \varphi_{x'}(t,\xi,\xi'))x' + (q(t) - \varphi_x(t,\xi,\xi'))x$,
$h(t) = \xi''(t) + (p(t) - \varphi_{x'}(t,\xi,\xi'))\xi'(t) + (q(t) - \varphi_x(t,\xi,\xi'))\xi(t)$,
$\tilde{r}(t,x,x')$ is C^1 smooth bounded function that coincides with $r(t,x,x')$ in some vicinity of $(t, \xi(t), \xi'(t),\ \ t \in [a,b]$.

The linear differential expression $(L_2x)(t)$ is of type n since a solution $\xi(t)$ is supposed to be of type n. □

We are in a position now to make more precise the "vague" term *essentially resonant BVP* used earlier.

If the second order BVP cannot be reduced to a quasi-linear form around each of its solutions (if any) then we will say that this problem is *essentially resonant.*

4 Conclusions

We arrived therefore at the following result.

Theorem 4.1 *The problem (1), (2) is essentially resonant if for some k it has a k-resonant solution. Otherwise either it has no solutions or it can be reduced to a quasi-linear problem around any of existing solutions.*

Abstract

Formulation for P and SV wave propagation through viscoelastic media, described by the Kelvin–Voigt model, using the generalized finite difference method is proposed. The stability of the proposed scheme is analyzed and a criterion to guarantee the stability is obtained. The star dispersion for both P and SV waves and group velocity are also analyzed.

A numerical example of a wave traveling on a bidimensional half-plane, initiated perpendicular to its free surface, is developed and solved. The obtained results are compared with its analytical solution.

Key words: Generalized finite difference method, Wave propagation, Viscoelasticity
MSC 2000: 65M06, 65M12

1 Introduction

Finite differences methods are numerical methods widely used for solving wave propagation problems. Traditionally, these methods are based on a mesh (discretization of the domain), but in the past decades meshless methods have been developed.

Generalized finite differences method (GFDM) is one of these finite differences methods that do not require a base mesh. It is based on moving least squares. The method approximates the value of the unkown function at a series of points within the domain (usually refered to as nodes). The derivatives of the function are linearized using a Taylor expansion, at each of these points. And therefore the problem is reduced to solving a linear system of equations. The current formulation of the method was presented by Liska and Orkisz[1] in 1998 and Benito et al. [2] provided in 2001, explicit formulae for the resolution of the problem.

The application of GFDM to wave propagation problems was introduced by Ureña et. al. [3]. They studied the star dispersion and stability for different type of waves [4] traveling through elastic domains. They also analyzed the simulation of absorbing boundary conditions, and obtained schemes for them, using perfectly matched layers (PML) [5].

The present paper proposes a formulation for including viscoelastic materials described by the Kelvin–Voigt model as the media through which the wave travels, considering the energy attenuation of the wave.

A scheme for GFDM is proposed and its stability is analyzed. A criterion to guarantee the stability is obtained. The star dispersion for both P and SV waves and group velocity are also analyzed.

Finally, a numerical example is proposed and solved. A wave is applied on the free surface of a bidimensional half-plane, perpendicular to its free surface. The obtained results are compared to its analytical solution.

2 Linear viscoelastic material

Certain materials behave in such a way that cannot be considered purely elastic or purely viscuous, but exhibit an intermediate behavior between both. In these viscoelastic materials the strains depend on time even without external forces applied. Stresses (represented by the tensor σ_{ij}) depend not only on strains but also on the velocity of deformation. Different models can be used to represent these relationships; in this article the Kelvin-Voigt model is used, which can be expressed for a bidimensional media as:

 ISBN: 978-84-617-8694-7

$$\begin{cases} \sigma_{xx} = \lambda\left(\dfrac{\partial u}{\partial x} + \dfrac{\partial w}{\partial z}\right) + \lambda t_r \dfrac{\partial}{\partial t}\left(\dfrac{\partial u}{\partial x} + \dfrac{\partial w}{\partial z}\right) + 2\mu\dfrac{\partial u}{\partial x} + 2\mu t_r \dfrac{\partial}{\partial t}\dfrac{\partial u}{\partial x} \\ \sigma_{zz} = \lambda\left(\dfrac{\partial u}{\partial x} + \dfrac{\partial w}{\partial z}\right) + \lambda t_r \dfrac{\partial}{\partial t}\left(\dfrac{\partial u}{\partial x} + \dfrac{\partial w}{\partial z}\right) + 2\mu\dfrac{\partial w}{\partial z} + 2\mu t_r \dfrac{\partial}{\partial t}\dfrac{\partial w}{\partial z} \\ \sigma_{xz} = \mu\left(\dfrac{\partial u}{\partial z} + \dfrac{\partial w}{\partial x}\right) + \mu t_r \dfrac{\partial}{\partial t}\left(\dfrac{\partial u}{\partial z} + \dfrac{\partial w}{\partial x}\right) \end{cases} \tag{1}$$

Where t_r is the relaxation time, λ the first Lamé parameter and μ the shear modulus.

$$\lambda = \frac{E\nu}{(1+\nu)(1-2\nu)}, \mu = G = \frac{E}{2(1+\nu)}, t_r = \frac{\eta}{E} \tag{2}$$

With ν as the Poisson ratio, E the elasticity modulus and η is the viscosity of the material.

3 Equations of motion

The general equations of motion of P-SV waves through a bidimensional (x-z plane) domain $\Omega \subset \mathbb{R}^2$ can be expressed, in absence of body forces, as:

$$\begin{cases} \rho\dfrac{\partial^2 U}{\partial t^2} = \dfrac{\partial \sigma_{xx}}{\partial x} + \dfrac{\partial \sigma_{xz}}{\partial z} \\ \rho\dfrac{\partial^2 W}{\partial t^2} = \dfrac{\partial \sigma_{zx}}{\partial x} + \dfrac{\partial \sigma_{zz}}{\partial z} \end{cases} \tag{3}$$

with the appropriate boundary conditions for each case.

U and W represent the displacements in two orthogonal directions and ρ is the densitiy of the medium.

By using the Lamé expressions to include the Kelvin-Voigt viscoelastic model into Eq.(3) the following expression in displacements is obtained.

$$\begin{cases} U_{tt} = & \alpha^2 U_{xx} + \beta^2 U_{zz} + (\alpha^2 - \beta^2) W_{xz} + t_r\Big(\alpha^2 U_{xx} + \beta^2 U_{zz} + \\ & +(\alpha^2 - \beta^2) W_{xz}\Big)_t \\ W_{tt} = & \alpha^2 W_{zz} + \beta^2 W_{xx} + (\alpha^2 - \beta^2) U_{xz} + t_r\Big(\alpha^2 W_{zz} + \beta^2 W_{xx} + \\ & +(\alpha^2 - \beta^2) U_{xz}\Big)_t \end{cases} \tag{4}$$

 ISBN: 978-84-617-8694-7

where α and β are the velocities of the P and SV waves respectively:

$$\begin{cases} \alpha = \sqrt{\dfrac{\lambda + 2\mu}{\rho}} \\ \beta = \sqrt{\dfrac{\mu}{\rho}} \end{cases} \tag{5}$$

4 Generalized finite differences method

4.1 Generalized finite differences scheme

The application of GFDM to media with elastic materials is completely developed in [6]. The methodology is breifly summarized hereafter.

A cloud of nodes is set within the domain Ω. In order to approximate the derivatives of the displacements by explicit linear expressions, a star is formed at each of these node. The star is made up by the node itself (center node) and a series of sourrounding nodes. The selection criteria for the nodes that form the star has already been studied by J.J. Benito et al. [2]

Let us consider a discretization D of the domain Ω, the inner node $(\mathbf{x}_0, t_n) \in D$ and the function ψ twice differentiable. Denoting the number of nodes of a star by N and the coefficients both the central node and the other nodes by m_{0ij} and m_{kij}, respectively, where $i, j \in \{x, z\}$ and $k \in \{1, ...N\}$, the linearization of each partial derivative is given by

$$\psi^n_{0,ij} = -m_{0ij}\psi^n_0 + \sum_{k=1}^{N} m_{kij}\psi^n_k \tag{6}$$

The temporal approximations are given by the following classical finite differences for first and second order, respectively

$$\psi^n_{0,t} = \frac{3\psi^n_0 - 4\psi^{n-1}_0 + \psi^{n-2}_0}{2\triangle t} \tag{7}$$

$$\psi^n_{0,tt} = \frac{\psi^{n-1}_0 - 2\psi^n_0 + \psi^{n+1}_0}{\triangle t^2} \tag{8}$$

Substituting (6), (7) and (8) in (4) and arranging terms, the scheme for P-SV waves in viscoelastic media is obtained

$$\begin{cases} u^{n+1}_0 = \sum\limits_{k=0}^{2}\left[A^{-k}_{u_0}u^{n-k}_0 + A^{-k}_{w_0}w^{n-k}_0 + \sum\limits_{j=1}^{N}\left(A^{-k}_{u_j}u^{n-k}_j + A^{-k}_{w_j}w^{n-k}_j\right)\right] \\ w^{n+1}_0 = \sum\limits_{k=0}^{2}\left[B^{-k}_{w_0}w^{n-k}_0 + B^{-k}_{u_0}u^{n-k}_0 + \sum\limits_{j=1}^{N}\left(B^{-k}_{w_j}w^{n-k}_j + B^{-k}_{u_j}u^{n-k}_j\right)\right] \end{cases} \tag{9}$$

 ISBN: 978-84-617-8694-7

where the coefficients are

$$\begin{cases} A_{u_0}^0 = 2 - (\triangle t^2 + 1.5t_r\triangle t)(\alpha^2 m_{0xx} + \beta^2 m_{0zz}) \\ A_{u_0}^{-1} = -1 + 2t_r\triangle t(\alpha^2 m_{0xx} + \beta^2 m_{0zz}) \\ A_{u_0}^{-2} = -0.5t_r\triangle t(\alpha^2 m_{0xx} + \beta^2 m_{0zz}) \\ A_{w_0}^0 = B_{u_0}^0 = -(\triangle t^2 + 1.5t_r\triangle t)(\alpha^2 + \beta^2)m_{0xz} \\ A_{w_0}^{-1} = B_{u_0}^{-1} = 2t_r\triangle t(\alpha^2 + \beta^2)m_{0xz} \\ A_{w_0}^{-2} = B_{u_0}^{-2} = -0.5t_r\triangle t(\alpha^2 + \beta^2)m_{0xz} \\ A_{u_j}^0 = (\triangle t^2 + 1.5t_r\triangle t)(\alpha^2 m_{jxx} + \beta^2 m_{jzz}) \\ A_{u_j}^{-1} = -2t_r\triangle t(\alpha^2 m_{jxx} + \beta^2 m_{jzz}) \\ A_{u_j}^{-2} = 0.5t_r\triangle t(\alpha^2 m_{jxx} + \beta^2 m_{jzz}) \\ A_{w_j}^0 = B_{u_j}^0 = (\triangle t^2 + 1.5t_r\triangle t)(\alpha^2 + \beta^2)m_{jxz} \\ A_{w_j}^{-1} = B_{u_j}^{-1} = -2t_r\triangle t(\alpha^2 + \beta^2)m_{jxz} \\ A_{w_j}^{-2} = B_{u_j}^{-2} = 0.5t_r\triangle t(\alpha^2 + \beta^2)m_{jxz} \\ B_{w_0}^0 = 2 - (\triangle t^2 + 1.5t_r\triangle t)(\alpha^2 m_{0zz} + \beta^2 m_{0xx}) \\ B_{w_0}^{-1} = -1 + 2t_r\triangle t(\alpha^2 m_{0zz} + \beta^2 m_{0xx}) \\ B_{w_0}^{-2} = -0.5t_r\triangle t(\alpha^2 m_{0zz} + \beta^2 m_{0xx}) \\ B_{w_j}^0 = (\triangle t^2 + 1.5t_r\triangle t)(\alpha^2 m_{jzz} + \beta^2 m_{jxx}) \\ B_{w_j}^{-1} = -2t_r\triangle t(\alpha^2 m_{jzz} + \beta^2 m_{jxx}) \\ B_{w_j}^{-2} = 0.5t_r\triangle t(\alpha^2 m_{jzz} + \beta^2 m_{jxx}) \end{cases} \tag{10}$$

4.2 Stability

We apply the Von Neumann method in the following harmonic waves

$$\begin{cases} u = a\exp(i(\omega t - \mathbf{k}^T\mathbf{x})) \\ w = b\exp(i(\omega t - \mathbf{k}^T\mathbf{x})) \end{cases} \tag{11}$$

where a and b are amplitudes, ω the angular frequency, $\mathbf{k} = (k_x, k_z)$ the wavenumber vector and $\mathbf{x} = (x, z) \in D$. For each star and time and denoting $\xi = \exp(i\omega\triangle t)$,

$$\begin{cases} u_0^n = a\xi^n\exp(-i\mathbf{k}^T\mathbf{x}_0) \\ u_j^n = a\xi^n\exp(-i\mathbf{k}^T\mathbf{x}_j) \\ w_0^n = b\xi^n\exp(-i\mathbf{k}^T\mathbf{x}_0) \\ w_j^n = b\xi^n\exp(-i\mathbf{k}^T\mathbf{x}_j) \end{cases} \tag{12}$$

 ISBN: 978-84-617-8694-7

We substitute (12) in (9), we denote $\mathbf{h}_j = \mathbf{x}_j - \mathbf{x}_0$ and we take into account that $m_{0xx} = \sum_{j=1}^{N} m_{jxx}$, $m_{0zz} = \sum_{j=1}^{N} m_{jzz}$ and $m_{0xz} = \sum_{j=1}^{N} m_{jxz}$. Then dividing by $\xi^n \exp(-i\mathbf{k}^T\mathbf{x}_0)$ and arranging terms, the following is obtained

$$\begin{cases} a\Gamma = b\Phi \Rightarrow \frac{a}{b} = \frac{\Phi}{\bar{\Gamma}} \\ \\ b\bar{\Gamma} = a\Phi \Rightarrow \frac{a}{b} = \frac{\bar{\Gamma}}{\Phi} \end{cases} \Rightarrow \Gamma\bar{\Gamma} = \Phi^2 \tag{13}$$

where

$$\begin{cases} \Gamma = \xi - \sum\limits_{k=0}^{2} \xi^{-k} \left(A_{u_0}^{-k} + \sum\limits_{j=1}^{N} A_{u_j}^{-k} \exp(-i\mathbf{k}^T\mathbf{h}_j) \right) \\ \bar{\Gamma} = \xi - \sum\limits_{k=0}^{2} \xi^{-k} \left(B_{w_0}^{-k} + \sum\limits_{j=1}^{N} B_{w_j}^{-k} \exp(-i\mathbf{k}^T\mathbf{h}_j) \right) \\ \Phi = \sum\limits_{k=0}^{2} \xi^{-k} \sum\limits_{j=1}^{N} A_{w_j}^{-k} (-1 + \exp(-i\mathbf{k}^T\mathbf{h}_j)) \end{cases} \tag{14}$$

The following notations are considered

$$\begin{cases} P = \sum\limits_{j=1}^{N} (\alpha^2 m_{jxx} + \beta^2 m_{jzz})(1 - \exp(-i\mathbf{k}^T\mathbf{h}_j)) \\ Q = \sum\limits_{j=1}^{N} (\alpha^2 m_{jzz} + \beta^2 m_{jxx})(1 - \exp(-i\mathbf{k}^T\mathbf{h}_j)) \\ R = \sum\limits_{j=1}^{N} (\alpha^2 - \beta^2) m_{jxz} (1 - \exp(-i\mathbf{k}^T\mathbf{h}_j)) \\ \chi = \dfrac{2\triangle t}{t_r} \cdot \dfrac{-\xi^3 + 2\xi^2 - \xi}{p\xi^2 - 4\xi + 1} \end{cases} \tag{15}$$

where $p = 3 + 2\frac{\triangle t}{t_r}$.

Operating, the following second order equation in χ is obtained

$$\begin{aligned} \Gamma\bar{\Gamma} = \Phi^2 \Rightarrow (\chi - \triangle t^2 P)(\chi - \triangle t^2 Q) = (\triangle t^2 R)^2 \Rightarrow \\ \Rightarrow \chi^2 - \triangle t^2 (P+Q)\chi + \triangle t^4 (PQ - R^2) = 0 \end{aligned} \tag{16}$$

and the solution is

$$\chi = \frac{\triangle t^2}{2} \left(P + Q + \sqrt{(P-Q)^2 + 4R^2} \right) \tag{17}$$

Denoting $\Upsilon = P + Q + \sqrt{(P-Q)^2 + 4R^2}$

 ISBN: 978-84-617-8694-7

$$\chi = \frac{\triangle t^2}{2}\Upsilon \tag{18}$$

Taking into account that $|\xi| \leq 1$ and using conservative criteria, a stability criterion is achieved

$$\triangle t \leq -2t_r + 2\sqrt{t_r^2 + \frac{2}{(\alpha^2+\beta^2)[(m_{0xx}+m_{0zz}) + \sqrt{(m_{0xx}+m_{0zz})^2 + 4m_{0xz}^2}]}} \tag{19}$$

4.3 Star dispersion for P and SV waves

From (18) and calling $\Theta = \frac{t_r \triangle t}{4}\Upsilon$, the following equation is obtained

$$\xi^3 + (p\Theta - 2)\xi^2 + (1 - 4\Theta)\xi + \Theta = 0 \tag{20}$$

Denoting

$$\begin{cases} \triangle_0 = (p\Theta - 2)^2 + 12\Theta - 3 \\ \triangle_1 = 2(p\Theta - 2)^3 + 36p\Theta^2 - (9p + 45)\Theta + 18 \\ \triangle_2 = \sqrt[3]{\dfrac{\triangle_1 + \sqrt{\triangle_1^2 - 4\triangle_0^3}}{2}} \end{cases} \tag{21}$$

the solution of (20) is

$$\xi_k = -\frac{1}{3}\left(p\Theta - 2 + \zeta^k \triangle_2 + \frac{\triangle_0}{\zeta^k \triangle_2}\right) \tag{22}$$

being $\zeta = -\frac{1}{2} + \frac{\sqrt{3}}{2}i$ and $k \in \{0, 1, 2\}$.

As $\xi = \exp(i\omega\triangle t)$, isolating ω_k we obtain $\omega_k = \frac{Arg(\xi_k)}{\triangle t}$ and therefore

$$\omega_{GFD} = \min_{k\in\{0,1,2\}} |\omega_k - \omega| = \frac{Arg(\xi)}{\triangle t} \tag{23}$$

This way, the velocity ratios for both waves are

$$\begin{cases} \dfrac{\alpha_{GFD}}{\alpha} = \dfrac{\lambda_P Arg(\xi)}{2\pi\alpha\triangle t} \\ \dfrac{\beta_{GFD}}{\beta} = \dfrac{\lambda_{SV} Arg(\xi)}{2\pi\beta\triangle t} \end{cases} \tag{24}$$

where λ_P and λ_{SV} are the wavelengths of P and SV waves, respectively.

 ISBN: 978-84-617-8694-7

4.4 Star dispersion for group velocity

First of all, we consider the following derivatives

$$\begin{cases} P_{\mathbf{k}} = i\sum_{j=1}^{N}(\alpha^2 m_{jxx} + \beta^2 m_{jzz})\exp(-i\mathbf{k}^T\mathbf{h}_j)\mathbf{h}_j \\ Q_{\mathbf{k}} = i\sum_{j=1}^{N}(\alpha^2 m_{jzz} + \beta^2 m_{jxx})\exp(-i\mathbf{k}^T\mathbf{h}_j)\mathbf{h}_j \\ R_{\mathbf{k}} = i\sum_{j=1}^{N}(\alpha^2 - \beta^2) m_{jxz}\exp(-i\mathbf{k}^T\mathbf{h}_j)\mathbf{h}_j \\ \Upsilon_{\mathbf{k}} = P_{\mathbf{k}} + Q_{\mathbf{k}} + \dfrac{(P-Q)(P_{\mathbf{k}} - Q_{\mathbf{k}}) + 4RR_{\mathbf{k}}}{\sqrt{(P-Q)^2 + 4R^2}} \\ \Theta_{\mathbf{k}} = \dfrac{t_r \triangle t}{4}\Upsilon_{\mathbf{k}} \\ \triangle_{0,\mathbf{k}} = (2p^2\Theta - 4p + 12)\Theta_{\mathbf{k}} \\ \triangle_{1,\mathbf{k}} = [6p(p\Theta - 2)^2 + 72p\Theta - 9p - 45]\Theta_{\mathbf{k}} \\ \triangle_{2,\mathbf{k}} = \dfrac{1}{6}\sqrt[3]{\left(\dfrac{2}{\triangle_1 + \sqrt{\triangle_1^2 - 4\triangle_0^3}}\right)^2}\left(\triangle_{1,\mathbf{k}} + \dfrac{\triangle_1\triangle_{1,\mathbf{k}} - 6\triangle_0\triangle_{0,\mathbf{k}}}{\sqrt{\triangle_1^2 - 4\triangle_0^3}}\right) \\ \xi_{\mathbf{k}} = -\dfrac{1}{3}\left(\Theta_+\zeta^k\triangle_{2,\mathbf{k}} + \dfrac{\triangle_{0,\mathbf{k}}\zeta^k\triangle_2 - \triangle_0\zeta^k\triangle_{2,\mathbf{k}}}{\zeta^{2k}\triangle_2^2}\right) = Re(\xi_{\mathbf{k}}) + iIm(\xi_{\mathbf{k}}) \end{cases} \tag{25}$$

where the value of k in the last case is the same that the value chosen in (23).

The group velocity is $v^g = \nabla_{\mathbf{k}}\omega = \dfrac{Im(\xi_{\mathbf{k}})Re(\xi) - Im(\xi)Re(\xi_{\mathbf{k}})}{\triangle t}$

5 Numerical example

The previously developed scheme is applied to a numerical example.

The domain is the $z > 0$ subspace with a boundary condition at $y = 0$ defined as a free surface with a normal wave applied, moving through the x direction with a velocity v:

$$\begin{cases} \sigma_{xz}(z=0) = 0 \\ \sigma_{zz}(z=0) = -p_0 \cdot exp(iC(x - v\cdot t)) \end{cases} \tag{26}$$

The previous boundary condition only uses the real part of the expresion, as the stress (σ_{zz}) is a real quantity. The real part of all quantities should be taken to obtain physically meaningful results.

 ISBN: 978-84-617-8694-7

The problem is solved and its analytical solution is obtained in [7].

A cloud of 19076 nodes is generated for a 5.00 m x 1.50 m domain and the GFDM is applied to solve the problem for this particular case. The maximum distance between nodes is 0.0283 m. The criterion for the selection of star nodes is the quadrant criterion (see [2]).

Hysteretic damping is considered, assuming that the product $\omega \cdot t_r$ is constant, and therefore the hysteretic damping ratio is $h = \omega t_r/2$, being $\omega = C \cdot v$ the frequency of the loading.

By using a null Poisson's ratio all the material properties can be expressed as a function of β and the results can therefore be normalized.

Applying the stability criterion, the maximum time step can be obtained: $\Delta t_{max} = 6.67 \cdot 10^{-5}$. A time step of $\Delta t = 4.20 \cdot 10^{-5} < \Delta t_{max}$ is used, for 5000 calculation steps.

Figure 1 represents movement amplitud versus velocity. Dimensionless variables have been used, showing the ratio of the dynamic amplitude to the static amplitude (for $v = 0$) and the ratio of the velocity of the wave v to the velocity of the shear waves β. Different curves have been obtained for different damping ratios. Dashed lines show the results obtained using the GFDM and continuous lines are used to represent the analyitical solution.

As it can be seen, the obtained results using GFDM match very accurately the analytical solution. The maximum deviation from the analytical solution is obtained for $h = 0.3$ and its value is $|1 - \mathrm{w}_{GFDM}/\mathrm{w}_{Analytical}| = 4.5\%$.

6 Conclusions

Formulation for P and SV wave propagation through viscoelastic media, described by the Kelvin–Voigt model, using the generalized finite difference method has been proposed.

The stability of the scheme is analyzed, obtaining a criterion valid to guarantee this stability.

Also, the star dispersion for both P and SV waves and group velocity are analyzed, and expressions for the dispersions are obtained.

A numerical example has been developed and compared with its analytical solution, showing the validity of the presented method and its application.

Abstract

This paper presents an efficient parallel implementation of the Active-Set Newton Algorithm (ASNA) for overcomplete non-negative representations of audio, which performance has been proved in previous works against other state of the art methods. The implementation presented in the paper has been developed in C, using parallel programming techniques to obtain a better performance in multicore architectures than the original MATLAB implementation.

Key words: non-negative matrix factorization, Newton algorithm, convex optimization, sparse representation, multicore, parallel computing

1 Introduction

The Active-Set Newton Algorithm (ASNA) presented in [1, 2] is an algorithm designed to minimize the Kullback-Leibler divergence for non-negative decomposition, which have been widely used in audio processing, for example on source separation [3], automatic music transcription [4], and sound event detection [5]. The KL divergence between vectors x and $\acute{x}$ is defined as

$$KL(x||\acute{x}) = \sum_i d(x_i, \acute{x_i})$$

where function d corresponds to

$$d(p,q) = \begin{cases} p\ log(p/q) - p + q) & p > 0 \text{ and } q > 0 \\ q & p = 0 \\ \infty & p > 0 \text{ and } q = 0 \end{cases}$$

 ISBN: 978-84-617-8694-7

Observation vector is modelled as $x \approx v = Bw$ subject to $(w, B, x, v) \geq 0$ where $x \in \Re^f$ is the original observation, $v \in \Re^f$ is the approximation obtained form the decomposition, $w \in \Re^n$ are the the non-negative weights and $B \in \Re^{f \times n}$ is the precomputed dictionary, which contains n atoms.

In the original paper [1], ASNA algorithm showed its advantages against some state of the art algorithms like the expectation-maximization update rules [6] and the projected gradient algorithm [7, pp. 267-268] for the overcomplete case. Due to this, we decided to improve the existing MATLAB implementation in order to obtain an efficient parallel version suitable for shared memory multicore machines.

The structure of the paper is as follows. In Section 2 ASNA algorithm and its existing implementation is explained. In Section 3 the developed implementations are presented. Then, Section 4 shows some preliminary results and a brief comparison between implementations. Finally, in Section 5 the results and the ongoing work are discussed.

2 ASNA algorithm

The main principle of the ASNA algorithm is that it estimates and updates a set of "active" atoms that have non-zero weights. The active set is initialized with a single atom which alone gives the smallest divergence. Then, it finds the most promising atom not in the active set by identifying the atom whose weight derivative is the smallest, and adds it to the active set. The weights of the atoms in the active set are estimated using the Newton method where the step size is chosen to ensure non-negativity of the weights. Atoms whose weights become zero or negative are removed from the active set. The algorithm iterates until a convergence criterion is achieved or a maximum number of iterations given by the user are reached. A detailed view of the algorithm can is found in [1, Sec. III].

The existing implementation programmed in MATLAB, that can be found in [8], uses a more general model than the one shown in the original algorithm [1, pp. 5]. The extended model can work with multiple observations at time, becoming $X \approx V = WB$ subject to $(W, B, X, V) \geq 0$ where the rows of $X, V \in \Re^{o \times f}$ are the observations and the rows of $W \in \Re^{o \times n}$ are the non-negative weights of each corresponding observation. Note that the model is transposed. That model gets some advantages from the fact of computing multiple observations at a time.

A brief pseudocode of that implementation can be found in Algorithm 1. In that implementation the weights in the active set are represented by the nonzero elements in a sparse weight matrix W_A and the active atoms in the dictionary are represented by S_A.

Algorithm 1 Original ASNA implementation algorithm

Require: $X \in \Re^{o \times f}$ $B \in \Re^{n \times f}$.

return $W \in \Re^{o \times n}$
Normalize each dictionary atom to unity norm
Pre compute operations for the gradient computations
(some matrix operations in the gradient computation only depend on the entry data and can be precomputed for speed)
Initialize active set for each observation
(Active atoms have values in W_A and not active are 0)
for $i = 1$ **to** $maximunnumberofiterations$ **do**
  Find active atoms
  Compute $V = W_A S_A$
  $R = X/V$ (element wise)
  if $i \ mod \ 2 = 0$ **then**
    Compute gradient w.r.t all weights
    if $i \ mod \ 10 = 0$ **then**
      Check convergence for non converged observations
      Remove converged observations from the computations
      if all observation have converged **then**
        Scale back W and exit
      end if
    end if
    Mark as 0 the gradient of the already active weights
    Add the atom with the minimum gradient of each observation
    to the active set, adding a small number to W_A
  end if
  Compute $R2 = X/V^2$ (element wise)
  Find the indexes of the active atoms
  Compute sparse product $Rcov = RS^T$
  for each observation not converged t **do**
    Find the active atoms of t
    if all gradients computed **then**
      Get $grad$ from the already computed gradients
    else
      Compute gradients w.r.t active atoms of t ($grad$)
    end if
    Compute Hessian GG
    Solve $GG \times searchDir = grad$
    Compute step size
    Update weights in W_A. If a weight becomes negative is removed.
  end for

3 Proposed algorithms

The first step was to improve the existing MATLAB implementation, then we implemented a parallel version of the algorithm in C programming language using HPC mathematical libraries. Finally, we implemented a parallel version of the algorithm using threading with OPENMP. In order to save space, the full algorithm for each proposed implementation is not written in the paper and only the most important changes will be explained. The source code of all proposed implementations can be found in [9].

3.1 Improved MATLAB implementation

The improved MATLAB implementation has some modifications that affect positively to the performance of the algorithm.

The first change was transposing the problem, most of the operations in the original implementation were made row-wise while MATLAB uses a column-wise memory arrangement. Transposing the problem allows the algorithm to do its operations column-wise taking advantage of MATLAB's memory arrangement. The second modification was changing some conditionals that were checking the existence of a variable containing all gradients to boolean variables, what caused a surprising improve in the performance. Then the sparse product function in line 23 was reworked to use both matrices in column-wise order and the system of equations solving in line 32 was solved directly using the Cholesky decomposition instead of using the default MATLAB solver. Finally, some minor tweaks and structural changes were done to improve performance and code readability.

3.2 C implementation

The authors chose the C programming language because it is much more efficient than MATLAB and has a better performance, despite being more difficult for the developer. The C implementation uses the Intel Math Kernel Library (MKL) which implements the BLAS and LAPACK computational interfaces in a very efficient way for Intel architectures.

The implementation is based on the improved MATLAB implementation and uses all improvements explained in Section 3.1. In this implementation the weight matrix is stored in memory as a full matrix, and the atoms in the active set are controlled by a double linked list of "atoms" for each observation. Each "atom" contains a link to the adjacent active atoms and the index of that atom in the full matrix in memory. Using this strategy the algorithm still can compute the sparse products in lines 7 and 23 without the need of finding the active atoms each time (lines 6 and 22), reducing the computation time needed for the sparse products. When removing active atoms in line 34 the atom should be removed from the atom list of observation t.

The second main improvement is that the sparse product on line 23, the computation of

 ISBN: 978-84-617-8694-7

$R2$ (line 21), the computation of the gradient (line 29) and the computation of the Hessian (line 31) have been mixed in a single computation. All these operations use the same data, so mixing the computations in the proper way diminishes the number of memory accesses and operations.

Finally, the system of linear equations in line 32 has been solved by mean of the LAPACK functions DPOTRF and DPOTRS. The first function computes the Cholesky factorization of a symmetric and positive definite matrix, while the second function uses the factor computed by DPOTRF to solve a triangular system of linear equations. Note that the function DPOTRF is threaded inside the MKL library, that means that in a multicore architecture it will benefit from the multiple cores increasing the algorithm performance. This function is one of the most costly parts of the algorithm, and this is why we do not call sequential to the non-parallel implementation.

3.3 Parallel C implementation

The parallel implementation of the ASNA algorithm takes advantage of the data independence between all the observations. Due to this, all observations can be processed in parallel. For the parallel implementation we used the OpenMP pragma"parallel for" for all loops which iterate along the observations. These loops correspond to lines 4, 7, 18, 19 and 24 . The schedule chosen is dynamic because during the iterative progression of the algorithm the already converged observations are removed from the computations, so the thread that tries to compute an already converged observation will skip it. The dynamic scheduling improves the performance for unbalanced load situations like that.

As said in Section 3.2 the DPOTRF functions is already threaded inside the library, but in the parallel version is going to be called sequentially for each observation. That fact will impact the speedup between both versions.

4 Experimental results

The experimental environment consists of a multicore machine with two Intel Xeon E5-2697 V2 (2,7GHz) with 12 physical cores each and 128 GB RAM. By the software side, the machine has MATLAB R2015b and the Intel parallel studio 2017 (contains icc v17.0.1 and MKL v2017) installed. All the test were executed using the 24 cores available.

In all proposed versions the KL divergence value obtained is the same, and equal to the KL divergence obtained by the original MATLAB implementation. Due to this, we are not going to evaluate the KL divergence value in this paper.

To keep the same structure of the experiments as in the original ASNA paper [1], all implementations were tested with three different dictionary sizes (100, 1000 and 10000) until convergence was achieved. Table 1 shows the execution times of all versions for all

 ISBN: 978-84-617-8694-7

three dictionary sizes and 130 observations at a time. The times had been obtained by averaging 100 different executions.

	Dictionary size		
ASNA algorithm implementation	100	1000	10000
Original MATLAB implementation	1,99	6,23	22,92
Improved MATLAB implementation	1,03	3,93	13,80
C implementation	0,34	1,64	5,96
Parallel C implementation	0,03	0,32	1,75

Table 1: Execution time of each ASNA implementation for different dictionary sizes computing 130 observations (seconds).

5 Discussion

The experimental results show a big improvement in the performance of the algorithms by using the proposed versions. Furthermore, with the parallel version, we can compute the whole model for the biggest dictionary analysed in less time than the needed using the smallest dictionary in the original ASNA version. If only one observation needs to be computed, due to the internal parallelism of the MKL library , the algorithm will still benefit from the multicore architecture.

Non-negative sparse representations have recently been used in many audio processing problems. However, their use in practical applications has been so far limited because of their high computational complexity. In paper we show that that the computational complexity of state-of-the-art ASNA algorithm, which itself is significantly faster than the established EM algorithm, can be reduced by more than 10 times. This makes the algorithm appealing for real-time applications such as speech enhancement.

In future works deeper tests will be done using bigger dictionaries. Furthermore, due to the trivial parallelism of the multiple observations model a GPU version of the algorithm can be implemented to speed up the process even more.

Abstract

The accuracy of a binary classification test based on a quantitative variable is usually measured by the total or the partial area under the receiver operating characteristic (ROC) curve. However, in practice a single cut-off point is used and, therefore, only the accuracy at that specific point is needed. Two different ways of determining the optimal cut-off point are the maximization of the Youden's index and the minimization of the distance between this point and the ideal point, which corresponds to the absence of misclassification. In this work a simulation study is performed in order to compare these measures and highlight the advantages and disadvantages of each procedure.

Key words: Cut-off point, ROC curve, Sensitivity, Specificity, Youden's index.
MSC 2000: 62P10

1 Introduction

A diagnostic test is performed to achieve a binary classification (e.g. healthy versus infected) based on the observed value of a quantitative variable. Thus, if this observed value exceeds a given threshold (the cut-off point), the individual is classified as infected (a positive result).

 ISBN: 978-84-617-8694-7

Otherwise, he is classified as healthy (a negative result). Unfortunately, almost all tests may result in misclassification: the occurrence of false negatives and false positive results. The usual applied measures to evaluate the classification accuracy are the specificity φ_e, which corresponds to the probability of getting a negative result from a healthy individual, and the sensitivity φ_s that is defined as the probability of getting a positive result from an infected individual. Hence, these probabilities depend on the value considered for the cut-off point. Furthermore, when applying the same classification test those measures are inversely correlated, since increasing one of them implies a decrease in the other.

2 The receiver operating characteristic (ROC) curve

The receiver operating characteristic (ROC) curve allows to observe the value of the sensitivity and the specificity when the cut-off point ranges from one end, in which all individuals are classified as infected, to the other extreme where all individuals are classified as healthy (i.e., at every possible cut-off point). Thus, the ROC curve represents the set of points with coordinates $(1-\varphi_e, \varphi_s)$. This curve enables the visualization of the optimal cut-off point in a test, the evaluation of the test's accuracy, as well as the comparison of different tests' performances [3, 4, 9, 16].

The area under the ROC curve (AUC) is usually applied to measure the accuracy of the binary classification method [3, 4, 9, 10, 16, 18]. Nevertheless, usually only a specific cut-off point is used, instead of all its possible values. Therefore, methodologies based in the partial area under the ROC curve (pAUC) were also developed to measure the test's accuracy [1, 7, 8, 15]. Hence, in order to only use the values of interest, those measures use the area under the ROC curve over a range of high specificity (or sensitivity) values to assess the diagnostic accuracy [5].

In the context of compound tests, in [13, 14] was proposed the use of the probability ϕ, which verifies $\varphi_s = \varphi_e = \phi$ for some cut-off point, to measure the test's performance. In the use of count distributions, this value may not exist, therefore, the distance between φ_s and φ_e shall be minimized and $\phi = \frac{\varphi_s + \varphi_e}{2}$. In fact, this measure can be seen as the use of a specific point on the ROC curve, the result of its intersection with the straight line $\varphi_s = \varphi_e$.

3 The optimal cut-off point

The choice of the optimal cut-off point is a decision that depends on several factors, such as the severity of the infection, the risk of not diagnosing the infection, the side effects of the treatment, among others. Hence, it may be important to decide between having a larger sensitivity or a larger specificity.

Nevertheless, considering the absence of clinical factors that led to the choice of one of these measures over the other, the optimal cut-off point can be set by the optimization of

 ISBN: 978-84-617-8694-7

some criterion. Hence, it can be the value that maximizes the Youden's index $\varphi_e + \varphi_s - 1$ [2, 6, 12, 17], which also corresponds to the maximization of the sum $\varphi_e + \varphi_s$, or the value that minimizes the distance to the perfect test $\sqrt{(\varphi_e - 1)^2 + (\varphi_s - 1)^2}$ (minimum distance) [6, 11]. This last procedure will provide the point on the ROC curve that is the closest to the ideal case $(0, 1)$.

In fact, in the application of each test, the focus is the evaluation of the accuracy for a single cut-off point, which shall be the best one for our purposes. Thus, it is indeed critical to realize if a greater value in the previously mentioned accuracy's measures guarantee that the test will generate a better performance at the specific cut-off point used in the application of the diagnostic test.

4 An accuracy comparison by simulation

A simulation study was performed using the R software in order to compare the differences between the area and the partial area under the ROC curve as well as the index ϕ. Moreover, those results were compared with the obtained accuracy in the application of a specific cut-off point, namely when this point is determined by the maximum Youden's index or by the minimum distance to the ideal case. For the test design, different distributions for the characterization of the infected and healthy individuals were considered in the simulations, both discrete and continuous, as well as diverse sample sizes. The main goal is to assess the association between those accuracy measures and, therefore, to assess whether those measures are able to evaluate the same criterion of accuracy. Moreover, the advantages and disadvantages of each measure will be highlighted.

Abstract

In this work, a new tool, based on *The Convergence Plane* and other graphical and complex tools, that allows to study real and complex dynamics of iterative methods is presented. This tool can be used, inter alia, to find the elements of a family that have good convergence properties and discard the bad ones or to see how the basins of attraction change along the elements of the family. The uses and results obtained will be commented to show the applicability of the tool.

1 Introduction

In this work we are concerned with the problem of teaching advanced mathematics. The study of iterative methods for solving nonlinear equations is generally complicated for students. To give rise to the behavior of the iterates of a method starting on different initial points we will study the dynamical behavior of an iterative method. The dynamical properties related to an iterative method applied to polynomials give important information about its stability and reliability. Most of one-point iterative methods applied to polynomials generate a rational function. Consequently, we will focus our attention on studying rational functions. One of the main interests in this work is the study of the parameter spaces associated to families of iterative methods, which allows us to distinguish between the good and bad methods of the family in terms of its numerical properties.

 ISBN: 978-84-617-8694-7

2 Basic dynamical concepts

Firstly, we present some dynamical concepts of complex dynamics (see [1, 2, 3, 4, 5, 6, 7] and the references therein for more information). One of the most common problems in Mathematics is solving a nonlinear equation $f(z) = 0$, with $f : \mathbb{C} \to \mathbb{C}$. The solutions of theses equations cannot be solved in a direct way, except in very special cases. That is why most of the methods for solving these equations are iterative. From now on we define a rational function $R : \hat{\mathbb{C}} \to \hat{\mathbb{C}}$, where $\hat{\mathbb{C}}$ is the Riemann sphere. Notice that $R(z) = \frac{P(z)}{Q(z)}$ where $P(z)$, $Q(z)$ are polynomials with complex coefficients without common factors. Moreover, the degree of a rational function $R(z)$ is defined as the highest degree of $P(z)$, $Q(z)$.

We will analyze the phase plane of the map R by classifying the starting points from the asymptotic behavior of their orbits.

Definition 1 *The* orbit of a point $z_0 \in \hat{\mathbb{C}}$ *is defined as*

$$\mathcal{O}(z_0) = \{z_0, R(z_0), R^2(z_0), ..., R^n(z_0), ...\}.$$

In the dynamical study of rational functions, one of the most commonly found problems is to study the behavior of the orbits of a point $z_0 \in \hat{\mathbb{C}}$. If the orbit converges to some value it will be a fixed point of the rational function $R(z)$.

Definition 2 *A point $z_0 \in \hat{\mathcal{C}}$, is called a* fixed point *of $R(z)$ if it verifies that $R(z) = z$.*

There exist different types of fixed points depending on its associated multiplier $\mu = |R'(z_0)|$.

Definition 3 *Taking the associated multiplier into account a fixed point z_0 is called:*

- superattractor *if* $|R'(z_0)| = 0$
- attractor *if* $|R'(z_0)| < 1$
- repulsor *if* $|R'(z_0)| > 1$
- parabolic *if* $|R'(z_0)| = 1$.

The study of ∞ as a fixed point is a little bit different.

Definition 4 *∞ is a fixed point of a rational function $R(z)$ if and only if $z = 0$ is a fixed point of the function:*

$$F : z \to \frac{1}{R(\frac{1}{z})}.$$

Moreover, if ∞ is a fixed point of $R(z)$, the associated multiplier of it is $\mu = F'(0)$

 ISBN: 978-84-617-8694-7

Consequently, ∞ can be attractor or even superattractor. The fixed points of a rational function are special cases of periodic points which are defined as follows.

Definition 5 *A point $z_0 \in \hat{\mathbb{C}}$, is called a periodic point of period p, if $R^p(z_0) = z_0$ and $R^n(z_0) \neq z_0$ for each $n < p$.*

Notice that the orbit associated to a periodic point z_0 of period n has only n different terms.

Definition 6 *The orbit associated to a periodic point of period n is called an n-cycle.*

The multiplier associated to an n-cycle is the same for every point of the cycle

$$|(R^n)'(z_0)| = \cdots = |(R^n)'(z_n)| = |R'(z_0)||R'(z_1)| \cdots |R'(z_n)|.$$

As the fixed points the cycles can be classified by means of the value of the multiplier as

- *superattractor* if $|R'(z_0)| = 0$
- *attractor* if $|R'(z_0)| < 1$
- *repulsor* if $|R'(z_0)| > 1$
- and *parabolic* if $|R'(z_0)| = 1$.

Due to the form of the method, some fixed points can be different to the roots of the polynomial. These points are called *strange fixed points*.

Another important concept in the study of iterative methods is the notion of basin of attraction.

Definition 7 The basin of attraction *of an attracting fixed point α is defined as:*

$$\mathcal{A}(\alpha) = \{z_0 \in \hat{\mathbb{C}} \ : \ R^n(z_0) \to \alpha, \ n \to \infty\}.$$

On the other hand, it is also important the notion of critical point defined as follows.

Definition 8 *Let be $R(z)$ a rational function of degree d. A point $w \in \hat{\mathbb{C}}$ for which the cardinality of $R^{-1}(w)$ is lower than d, is called critical value of $R(z)$. A point $z \in R^{-1}(w)$ which is a root of $R(z) - w$ of multiplicity greater than 1, is called a critical point of $R(z)$. Moreover, ∞ is a critical point of $R(z)$ if 0 is a critical point of $F(z)$. The multiplicity of ∞ as critical point of $R(z)$ is the same as the multiplicity of 0 as critical point of $F(z)$.*

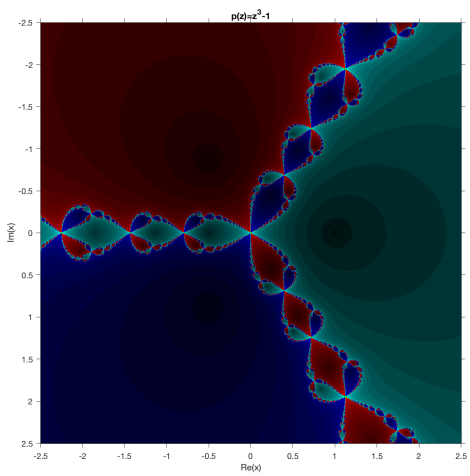
Remark 1 *A point z is a critical point of a holomorphic function $p(z)$ if $p'(z) = 0$.*

 ISBN: 978-84-617-8694-7

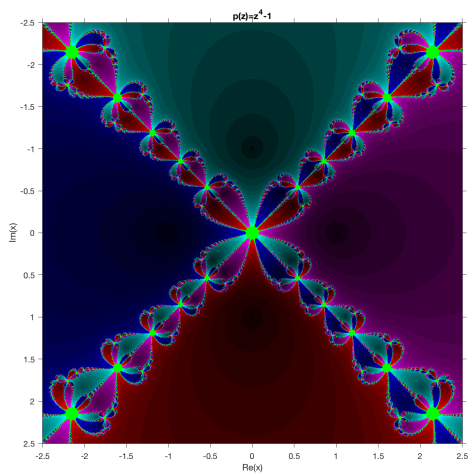
3 Graphical tool

Using all the preceding results we have developed a new tool in which we study the dynamical behavior of different iterative methods applied to polynomials:

- The authors need to introduce the degree of the polynomial, the coefficients and the definition of the iterative method the want to study.
- The program, using connections with the programs MATLAB and MATHEMATICA, gives the polynomial roots, the fixed points and its behavior and the critical points.
- Moreover, the program draws the basins of attraction in a region (which must be introduced previously by the author), as appears in Figure 1.
- On the other hand, in case of studying a family of methods or a family of polynomials, the program also draws the parameter planes.
- Even more, the program gives the possibility to study real and complex dynamics.



$p(z) = z^3 - 1$



$p(z) = z^4 - 1$

Figure 1: Dynamical planes for Newton's method applied to different polynomials.

Abstract

The purpose of this paper is a generalized strong variant of the Borwein-Preiss variational principle (see in [11]) for which a strong minimality holds in case the divergent series of positive numbers underlying a complete metric space, a generalized distance and a special class of perturbation by following an ideal of Kruger, et al. [9]. Furthermore, our main result extends and strengthens the strong Ekeland and Borwein - Preiss variational principles on a complete metric space in Georgive [6] and Li and Shi [10], respectively.

Key words: Banach spaces complete metric spaces Borwein-Preiss variational principle strong minimizers

1 Introduction

The Ekeland variational principle (for short, EVP) was discovered by Ekeland in 1974 [4]. There were many generalized and equivalent forms of the Ekeland's variational principle in [7, 16, 5, 12, 13, 17, 14]. One of the generalized Ekeland's variational principles is "the Borwein-Preiss variational principle" which was introduced by Borwein and Preiss in 1987 [1]. This principle is an important tool in finite dimensional nonsmooth analysis.

A counterpart of the principle subsequently found by Deville, Godefroy and Zizler in 1993 [3] but their result gives no information about the location of the strong minimizer, and offers no way to identify explicitly a perturbation g in [3]. Later, Li and Shi [10] extended

 ISBN: 978-84-617-8694-7

the Borwein-Preiss variational principle in case the divergent series of positive numbers to a complete metric space, and gave a simpler proof of Theorem 2.5. Very recently, Kruger et al. [9] refine and slightly strengthen the metric space version of the Borwein-Preiss variational principle due to Li and Shi. Moreover, they also clarify the assumptions and conclusions of [10] and [2] and streamline the proofs.

On the other hand, Loewen and Wang [11] constructed in the Banach space setting a special class of perturbations subsuming those used in Theorem 2.5, established strong minimality in the analogue of (1), and gave its applications. Their result is called "a strong variant of the Borwein-Preiss variational principle".

The purpose of this paper is a generalized strong variant of the Borwein-Preiss variational principle (see in [11]) for which a strong minimality holds in case the divergent series of positive numbers underlying a complete metric spacee, a generalized distance and a special class of perturbation by following an ideal of Kruger, et al. [9]. Furthermore, our main result extends and strengthens the strong Ekeland and Borwein - Preiss variational principles on a complete metric space in Georgive [6] and Li and Shi [10], respectively.

2 Preliminaries

We note that X is a complete metric space, E is a Banach space, $\mathbb{N}$ is the set of numbers, and $\mathbb{R}$ is the set of reals.

Definition 2.1 A function $\omega : X \times X \to [0, \infty)$ is called a w-distance on X if the following are satisfied:

1.) $\omega(x, z) \leq \omega(x, y) + \omega(y, z)$ for any $x, y, z \in X$;
2.) for any $x \in X$, $\omega(x, \cdot) : X \to [0, \infty)$ is lower semicontinuous;
3.) for any $\epsilon > 0$, there exists $\delta > 0$ such that $\omega(z, x) \leq \delta$ and $\omega(z, y) \leq \delta$ imply $d(x, y) \leq \epsilon$.

Definition 2.2 [15] Let $f : X \to \mathbb{R} \cup \{+\infty\}$.

a.) A point $\bar{x} \in X$ is said to be a strict minimizer of f if $f(\bar{x}) < f(x)$ for each $x \in X, x \neq \bar{x}$.
b.) A point $\bar{x} \in X$ is said to be a strong minimizer of f if $f(\bar{x}) = \inf_{x \in X} f(x)$ and each minimizing sequence for f is convergent to $\bar{x}$.

It is clear that each strong minimizer of f is also a strict minimizer. But the converse is false. For example, the point $\bar{x} = 0$ is a strict but not a strong minimizer of the function $f(x) := x^2 e^x$ on $\mathbb{R}$; notice that each sequence $\{x_n\}$ tending to $+\infty$ as $n \to \infty$ is a minimizing sequence for f. Recall that $diam(A) := sup\{\omega(x, y) | x, y \in A\}$ denotes the diameter of the set $A \subset X$.

Remark 2.3 [15] For $\epsilon > 0$ let

$$\Sigma_\epsilon(f) := \{x \in X | f(x) < \inf_X f + \epsilon\}.$$

 ISBN: 978-84-617-8694-7

The functional f has a strong minimizer on X if and only if

$$\inf\{diam(\Sigma_\epsilon(f))|\epsilon > 0\} = 0.$$

Theorem 2.4 Let X be a nonempty complete metric space and $\omega : X \times X \to [0, \infty)$ be a w-distance on X and $\omega(x, x) = 0$ for all $x \in X$. Let C_n be a decreasing sequence of nonempty closed sets with $\sup\{\omega(x, y)|\, x, y \in C_n\} \to 0$. Then the intersection of the C_n contains exactly one point:

$$\bigcap_{n=1}^{\infty} C_n = \{x\}$$

for some $x \in X$.

Proof For each k, let $x_k \in C_k$. Since $\sup\{\omega(x, y)|\, x, y \in C_n\} \to 0$ the sequence $\{x_k\}$ is Cauchy sequence. Since X is complete and $\{x_k\}$ is a Cauchy, then we have $x_k \to x$ for some $x \in X$. For any n, the subsequence $\{x_{n+k}\} = \{x, x_{n+2}, \ldots\} \to x$. Since $\{C_n\}$ is decreasing, this subsequence is inside the closed set C_n, so $x \in C_n$. Therefore $x \in \bigcap_{n=1}^{\infty} C_n$. If $x, y \in \bigcap_{n=1}^{\infty} C_n$, then $\omega(x, y) \leq \sup\{\omega(x, y)|\, x, y \in C_n\}$. Since $\sup\{\omega(x, y)|\, x, y \in C_n\} \to 0$, we get $\omega(x, y) = 0$. Thus $x = y$. Hence $\bigcap_{n=1}^{\infty} C_n = \{x\}$

Theorem 2.5 [1] Let E be a Banach space and $f : E \to \mathbb{R} \cup \{+\infty\}$ be a lower semicontinuous function bounded from below. Given $\epsilon > 0, \lambda > 0, p \geq 1$, and $z \in X$ satisfying

$$f(z) \;\leq\; \inf_{x \in E} f(x) + \epsilon.$$

Then, there exist a sequence $\mu_n > 0$, with $\sum_{n=1}^{\infty} \mu_n = 1$, and a point $v \in E$, expressible as the (norm-) limit of some sequence $\{v_n\}$, such that

$$f(x) + \frac{\epsilon}{\lambda} \triangle_p(x) > f(v) + \frac{\epsilon}{\lambda} \triangle_p(v) \quad \forall x \in E \setminus \{v\}, \tag{1}$$

where $\triangle_p(x) := \sum_{n=1}^{\infty} \mu_n \|x - v_n\|^p$. Moreover, $\|x_0 - v\| \leq \lambda$ and $f(v) \leq \epsilon + \inf_{x \in E} f(x)$. When E is a smooth space and $p > 1$, the perturbation function involved in (1) of the above theorem is smooth.

Remark 2.6 When $p = 1$, Theorem 2 essentially recaptures The Ekeland variational principle since $\triangle_1(x) - \triangle_1(v) \leq \|x - v\|$.

Theorem 2.7 [A strong variant of the Borwein-Preiss variational principle][11] Let E be a Banach space, a function $f : E \to \mathbb{R} \cup \{+\infty\}$ be a lower semicontinuous, $\epsilon > 0$, and $x_0 \in E$ be such that

$$f(x_0) < \inf_{x \in E} f(x) + \epsilon.$$

Assume that $\{\mu_n\}_{i=0}^{\infty} \in (0, 1)$ is a decreasing sequence with $\sum \mu_n < +\infty$, and $\rho : E \to [0, +\infty)$ is a continuous function satisfying

$$\rho(0) = 0, \;\; and \;\; \eta := \sup\{\|x\| : \bar{\rho}(x) < 1\} < +\infty. \tag{2}$$

 ISBN: 978-84-617-8694-7

Then, there exist a sequence $\{v_n\}$ in E and a function ρ_∞ such that $\lim_{i\to\infty} v_n = v \in X$ satisfies

(i) $\bar{\rho}(x_0 - v) < 1$,
(ii) $f(v) + \epsilon\rho_\infty(v) \leq f(x_0)$, and
(iii) v is a strong minimizer of $f + \epsilon\rho_\infty$.

3 A generalized strong Borwein-Preiss variational principle in a complete metric space

Now, we introduce a perturbation by shifting and scaling a given continuous function $\rho : \omega(X \times X) \to [0, +\infty)$ on which satisfies for every $x \in X$, and $\lambda > 0$

$$\rho(\omega(x, x)) = 0 \ \textit{and} \ \eta := \sup_{(x,v)\in(X\times X)} \{\omega(x, v) : \rho(\omega(x, v)) < \lambda\} < +\infty, \tag{3}$$

and set

$$\rho_\infty(x, \{v_i\}) := \sum_{i=0}^{\infty} \mu_i(i + 1)\rho(\omega(x, v_i)) \tag{4}$$

where for scalars $\mu_i \in (0, 2)$ and $\{v_i\}_{i=0}^{\infty} \subset X$.

The following theorem is a generalized strong Borwein-Preiss variational principle in case the series $\sum_{i=0}^{\infty} \mu_i$ is diverges underlying a complete metric space, generalized distance and special class of perturbation.

Theorem 3.1 Let (X, d) be a complete metric space, ω be a w-distance with $\omega(x, x) = 0$ such that $t \cdot \omega(X \times X) \subseteq \omega(X \times X)$ for all $t \in \mathbb{N}$, a function $f : X \to \mathbb{R} \cup \{+\infty\}$ be a lower semicontinuous, $\bar{x} \in X$, and $\epsilon > 0$ be such that

$$f(\bar{x}) < \inf_{x\in X} f(x) + \epsilon.$$

Suppose that $\rho : \omega(X \times X) \to [0, +\infty)$ is a continuous function define as in (3). Then for any $\lambda > 0$ and decreasing sequence $\{\mu_i\}_{i=0}^{\infty}$ in $(0, 2)$, there exist a sequence $\{v_i\}$ in X and a function ρ_∞ of the form (4) such that $\lim_{i\to\infty} v_i := v \in X$ satisfies

(i) $\rho(\omega(\bar{x}, v)) < \lambda/\mu_0, \quad (i + 1)\rho(\omega(v, v_i)) < \lambda/2^i\mu_0 \ (i = 1, 2, \ldots)$;
(ii) the series $\sum_{i=0}^{\infty} \mu_i(i + 1)\rho(\omega(v, v_i))$ is convergent and

$$f(v) + \epsilon\rho_\infty(v, \{v_i\}) \leq f(\bar{x}), \tag{5}$$

and v is a strong minimizer of $f + \epsilon\rho_\infty$ on X.
In particular case, if there exists $N \in \mathbb{N}$ such that $\mu_i = 0$ for all $i \geq N$, then

$$f(v) + \epsilon \sum_{i=0}^{N-1} \mu_i(i + 1)\rho(\omega(v, v_i)) \leq f(\bar{x}), \tag{6}$$

 ISBN: 978-84-617-8694-7

and v is a strong minimizer of $f + \epsilon\rho_{N-1}$ on X.

Proof Define sequences $\{v_i\}_{i=0}^{\infty}, \{f_i\}_{i=0}^{\infty}, \{S_i\}_{i=0}^{\infty}$, and $\{\mu_i\}_{i=0}^{\infty}$ is decreasing sequence, inductively starting with $v_0 = \bar{x}, f_0 = f$, and $f_1(x) := f_0(x) + \epsilon(\mu_0 + 1)\rho(\omega(x, v_0))$. By our assumption, we have $f_0(v_0) < \inf_{x\in X} f_0(x) + \epsilon$. Note that $\inf_X f_1 \leq f_1(v_0) = f_0(v_0)$. If $\inf_X f_1 = f_1(v_0) = f_0(v_0)$, we let $v_1 := v_0$. If $\inf_X f_1 < f_1(v_0)$, it follows by the definition of the infimum that there exists $v_1 \in X$ such that

$$\begin{aligned} f_1(v_1) &< \inf_X f_1 + \frac{\lambda(\mu_1 + \frac{1}{2})}{2^2(\mu_0 + 1)}(f_0(v_0) - \inf_X f_1) \\ &= \frac{\lambda(\mu_1 + \frac{1}{2})}{2^2(\mu_0 + 1)} f_0(v_0) + (1 - \frac{\lambda(\mu_1 + \frac{1}{2})}{2^2(\mu_0 + 1)}) \inf_X f_1 \\ &< f_0(v_0). \end{aligned}$$

Set

$$S_0 := \{x \in X | f_1(x) \leq f_1(v_1) + \frac{\lambda(\mu_0 + 1)\epsilon}{2^1(\mu_0 + 1)}\}. \tag{7}$$

Obviously, $v_1 \in S_0$. Since the function f_1 is lower semicontinuous, we get S_0 is closed. Thus, by induction, we have

$$\inf_X f_{i+1} \leq f_{i+1}(v_i) = f_i(v_i), \tag{8}$$

and

$$f_{i+1}(x) := f_i(x) + \epsilon\bar{\mu}_i(i + 1)\rho(\omega(x, v_i)), \forall x \in X, \tag{9}$$

where $\bar{\mu}_i := \mu_i + \frac{1}{i+1}$ for any $i = 0, 1, 2, \ldots$. Therefore, v_{i+1} can be chosen satisfying

$$f_{i+1}(v_{i+1}) \leq \frac{\lambda\bar{\mu}_{i+1}}{2^{i+2}\bar{\mu}_0} f_i(v_i) + (1 - \frac{\lambda\bar{\mu}_{i+1}}{2^{i+2}\bar{\mu}_0}) \inf_X f_{i+1} \leq f_i(v_i), \tag{10}$$

and

$$S_i := \{x \in X | f_{i+1}(x) \leq f_{i+1}(v_{i+1}) + \frac{\lambda\bar{\mu}_i\epsilon}{2^{i+1}\bar{\mu}_0}\}. \tag{11}$$

Since f_{i+1} is lower semicontinuous, the set S_i is closed. Moreover, S_i is nonempty as $v_{i+1} \in S_i$. Since $\bar{\mu}_{i+1}$ is a strictly decreasing sequence, $f_{i+1} \geq f_i$, it follows by (10) that

$$f_{i+1}(v_{i+1}) - \inf_X f_{i+1} \leq \frac{\lambda\bar{\mu}_{i+1}}{2^{i+2}\bar{\mu}_0}(f_i(v_i) - \inf_X f_{i+1}) \leq f_i(v_i) - \inf_X f_i. \tag{12}$$

We have $S_i \subseteq S_{i-1}$ for all $i = 1, 2, \ldots$. In fact, if $x \in S_i$, then we note by (10) that

$$f_i(x) \leq f_{i+1}(x) \leq f_{i+1}(v_{i+1}) + \frac{\lambda\bar{\mu}_i\epsilon}{2^{i+1}\bar{\mu}_0} \leq f_i(v_i) + \frac{\lambda\bar{\mu}_{i-1}\epsilon}{2^{i+1}\bar{\mu}_0} \tag{13}$$

 ISBN: 978-84-617-8694-7

and therefore $x \in S_{i-1}$. We will show that $diam(S_i) \to 0$ as $i \to \infty$. Since $f_{i-1} \leq f_i$, it follows by (10) (with i replaced by $i-1$) that

$$\begin{aligned} f_i(v_i) - \inf_X f_i &\leq \frac{\lambda\bar{\mu}_i}{2^{i+1}\bar{\mu}_0}(f_{i-1}(v_{i-1}) - \inf_X f_i) \\ &\leq \frac{\lambda\bar{\mu}_i}{2^{i+1}\bar{\mu}_0}(f_{i-1}(v_{i-1}) - \inf_X f_{i-1}) < \frac{\lambda\bar{\mu}_i\epsilon}{2^{i+1}\bar{\mu}_0}. \end{aligned} \tag{14}$$

The last $<$ follows from (12) and $f_0(v_0) - \inf_X f_0 = f(\bar{x}) - \inf_X f < \epsilon$. Now, let $x \in S_i$. By the definitions of S_i and f_{i+1}, we obtain

$$\begin{aligned} \bar{\mu}_i\epsilon(i+1)\rho(\omega(x, v_i)) &\leq f_{i+1}(v_{i+1}) - f_i(x) + \frac{\lambda\bar{\mu}_i\epsilon}{2^{i+1}\bar{\mu}_0} \\ &\leq f_{i+1}(v_{i+1}) - \inf_X f_i + \frac{\lambda\bar{\mu}_i\epsilon}{2^{i+1}\bar{\mu}_0}. \end{aligned} \tag{15}$$

By (15) with $f_{i+1}(v_{i+1}) \leq f_i(v_i)$ and (14), it can conclude that

$$(i+1)\rho(\omega(x, v_i)) < \frac{\lambda}{2^i\bar{\mu}_0} < \lambda, \quad \forall i = 0, 1, 2, \ldots \tag{16}$$

The hypothesis (3) therefore implies

$$(i+1)\omega(x, v_i) \leq \eta \Rightarrow \omega(x, v_i) \leq \frac{\eta}{i+1} \tag{17}$$

and so $diam(S_i) \leq \frac{2\eta}{i+1} \to 0$ as $i \to \infty$. By theorem 2, we note that $\bigcap_{i=0}^{\infty} S_i$ contains exactly one point, say v. For each i, we have $v_{i+1} \in S_i$ and $v \in S_i$. Hence $\omega(v_{i+1}, v) \to 0$ as $i \to \infty$. Moreover, by setting $x = v$ in (16), we have $\rho(\omega(\bar{x}, v)) < \frac{\lambda}{\bar{\mu}_0}$ when $i = 0$ and $(i+1)\rho(\omega(v, v_i)) < \frac{\lambda}{2^i\bar{\mu}_0}$ for every $i = 1, 2, \ldots$. Therefore (i) holds.

We now define

$$\tilde{S}_i := \{x \in X | f_{i+1}(x) \leq f_{i+1}(v_{i+1})\} \quad \forall i = 0, 1, 2, \ldots. \tag{18}$$

(ii) Since $f_{i+1} \geq f_i$ and $f_{i+1}(v_{i+1}) \leq f_i(v_i)$, we have $\tilde{S}_i \subseteq \tilde{S}_{i-1}$. Moreover, we note that each $\tilde{S}_i$ is a nonempty closed subset of S_i. By theorem 2, we have $\bigcap_{i=0}^{\infty} \tilde{S}_i = \{v\}$. This together with $f_{i+1}(v_{i+1}) \leq f_i(v_i)$ implies

$$f_n(v) \leq f_n(v_n) \leq f_i(v_i) \leq f_0(v_0) = f(\bar{x}), \quad \forall n > i. \tag{19}$$

From (9), we have

$$f_n(x) = f(x) + \epsilon\sum_{j=0}^{n-1} \bar{\mu}_j(j+1)\rho(\omega(x, v_j)), \quad x \in X. \tag{20}$$

 ISBN: 978-84-617-8694-7

According to (19) and (20), we get

$$\begin{aligned}\sum_{j=0}^{n}\mu_j(j+1)\rho(\omega(v,v_j)) &< \sum_{j=0}^{n-1}\bar{\mu}_j(j+1)\rho(\omega(v,v_j))\\ &= \frac{f_n(v)-f(v)}{\epsilon}\\ &\leq \frac{f(\bar{x})-f(v)}{\epsilon},\end{aligned} \tag{21}$$

for every $n\in\mathbb{N}$. This implies that $\sum_{j=0}^{\infty}\mu_j(j+1)\rho(\omega(v,v_j))$ is convergent. By the definition of ρ_∞ and (20), we conclude that

$$f(v)+\epsilon\rho_\infty(v,\{v_j\})=\lim_{n\to\infty}f_n(v)\leq f_i(v_i)\leq f(\bar{x}). \tag{22}$$

Hence, the condition (5) holds. Let $\tilde{f}:=f+\epsilon\rho_\infty$.

We are going to show that $\Sigma_{\frac{\epsilon\lambda\bar{\mu}_i}{2^{i+1}\bar{\mu}_0}}(\tilde{f})\subseteq S_i$ for each i. Suppose that $x\in\Sigma_{\frac{\epsilon\lambda\bar{\mu}_i}{2^{i+1}\bar{\mu}_0}}(\tilde{f})$. From (20) and (22), we have

$$f_{i+1}(x)\leq\tilde{f}(x)\leq\tilde{f}(v)+\frac{\epsilon\lambda\bar{\mu}_i}{2^{i+1}\bar{\mu}_0}\leq f_{i+1}(v_{i+1})+\frac{\epsilon\lambda\bar{\mu}_i}{2^{i+1}\bar{\mu}_0}. \tag{23}$$

This implies that $x\in S_i$ and therefore $\Sigma_{\frac{\epsilon\lambda\bar{\mu}_i}{2^{i+1}\bar{\mu}_0}})(\tilde{f})\subseteq S_i$ for each i. Moreover, it follows from $diam(S_i)\to 0$ as $i\to 0$ and $\Sigma_{\frac{\epsilon\lambda\bar{\mu}_i}{2^{i+1}\bar{\mu}_0}}(\tilde{f})\subseteq S_i$ that

$$\lim_{i\to\infty}diam(\Sigma_{\frac{\epsilon\lambda\bar{\mu}_i}{2^{i+1}\bar{\mu}_0}}(\tilde{f}))=0 \tag{24}$$

Since the sequence $\bar{\mu}_i$ is strictly decreasing, it follows that the sequence of the closed sets $\Sigma_{\frac{\epsilon\lambda\bar{\mu}_i}{2^{i+1}\bar{\mu}_0}}(\tilde{f})$ is strictly decreasing. Hence, by the Cantor's intersection theorem, $\bigcap_{i=0}^{\infty}\Sigma_{\frac{\epsilon\lambda\bar{\mu}_i}{2^{i+1}\bar{\mu}_0}}(\tilde{f})=\{v\}$. Moreover, it follows from remark 2 that v is a strong minimizer of $\tilde{f}$. Therefore, we can conclude that (ii) is true. In particular case, if there exists $N\in\mathbb{N}$ such that $\mu_i=0$ for all $i\geq N$, then

$$f(v)+\epsilon\sum_{i=0}^{N-1}\mu_i(i+1)\rho(\omega(v,v_i))\leq f(\bar{x}), \tag{25}$$

and v is a strong minimizer of $f+\epsilon\rho_{N-1}$ on X.

When reduced to Banach spaces, it extends and strengthens the strong variant of Borwein-Preiss variational principle on Banach spaces in Loewen and Wang (Theorem 2.7).

Corollary 3.2 Let E be a Banach space, a function $f:E\to\mathbb{R}\cup\{+\infty\}$ be a lower semicontinuous, $\epsilon>0$, and $\bar{x}\in E$ be such that

$$f(\bar{x})<\inf_{x\in E}f(x)+\epsilon.$$

 ISBN: 978-84-617-8694-7

Assume that for any $\lambda > 0, \{\mu_i\}_{i=0}^{\infty} \in (0,2)$ is a decreasing sequence, and $\bar{\rho} : E \to [0, +\infty)$ is a continuous function satisfying

$$\bar{\rho}(0) = 0, \ \ and \ \ \eta := \sup\{\|x\| : \bar{\rho}(x) < \lambda\} < +\infty. \tag{26}$$

Then, there exist a sequence $\{v_i\}$ in E and a function ρ_∞ such that $\lim_{i\to\infty} v_i := v \in X$ satisfies

(i) $\bar{\rho}(\bar{x} - v) < \lambda/\mu_0, \quad (i+1)\bar{\rho}(v - v_i) < \lambda/2^i\mu_0 \ (i = 1, 2, \ldots)$;

(ii) the series $\sum_{i=0}^{\infty} \mu_i \bar{\rho}((i+1)v - v_i)$ is convergent and

$$f(v) + \epsilon\rho_\infty(v) \le f(\bar{x}), \tag{27}$$

and v is a strong minimizer of $f + \epsilon\rho_\infty$ on E.

In particular case, if there exists $N \in IN$ such that $\mu_i = 0$ for all $i \ge N$, then

$$f(v) + \epsilon \sum_{i=0}^{N-1} \mu_i \bar{\rho}((i+1)v - v_i) \le f(\bar{x}), \tag{28}$$

and v is a strong minimizer of $f + \epsilon\rho_{N-1}$ on E.

Proof Setting

$$\rho(\omega(x,y)) := \bar{\rho}(x - y), \quad and \quad \eta := \sup_{(x,v)\in X\times X} \{\omega(x,v) \mid \rho(\omega(x,v)) < \lambda\} \tag{29}$$

for any $x, y \in E$. Note that

$$\begin{aligned} \sup_{(x,v)\in X\times X} \{\omega(x,v) \mid \rho(\omega(x,v)) < \lambda\} &= \sup_{(x,-v)\in X\times X} \{\|x - v\| \mid \|x - v\| < \lambda\} \\ &= \sup_{u\in X} \{\|u\| \mid \bar{\rho}(u) < \lambda\} \\ &= \eta < +\infty. \end{aligned}$$

Then, by Theorem 3.1, we conclude that (i) and (ii) hold.

Next, we give an example for illustrating our main result (Theorem 3.1).

Example 3.4 Let $X = (-\infty, -1] \cup [1, +\infty)$ and $f : X \to \mathbb{R}^+$ be a lower semicontinuous function defined by

$$f(a) := a^2, \ \forall a \in X. \tag{30}$$

Let $\epsilon = \frac{1}{2}, \ \lambda = 1$, and $\bar{x} \in X$. Assume that $\rho : \omega(X \times X) \to [0, +\infty)$ is a continuous function defined by

$$\rho(\omega(b,c)) := \omega(b,c) = || \ b \mid - c \mid \quad forall \ \ b, c \in X. \tag{31}$$

By Theorem 3, for any decreasing sequence $\{\mu_i\}_{i=0}^{\infty}$ in $(0,2)$, there exists a sequence $\{v_i\}_{i=0}^{\infty} \in X$ which $v_i = \sqrt{\bar{x}^2 - \frac{1}{2}} + \frac{\lambda}{2^i\mu_0(i+1)^2}$ converges to some $v = \sqrt{\bar{x}^2 - \frac{1}{2}}$ in X such that

$$\rho(\omega(\bar{x}, v)) = \omega(\bar{x}, \sqrt{\bar{x}^2 - \frac{1}{2}}) = || \ \bar{x} \mid - \sqrt{\bar{x}^2 - \frac{1}{2}} \ | < 1. \tag{32}$$

 ISBN: 978-84-617-8694-7

Suppose that $\mu_i = \frac{1}{i+1}$ for any $i = 0, 1, 2, \ldots$, we have

$$(i+1)\rho(\omega(v, v_i)) = \omega(v, v_i) = (i+1) \mid -\frac{1}{2^i(i+1)^2} \mid < \frac{1}{2^i}. \tag{33}$$

Next, we consider

$$\begin{aligned} f(v) + \epsilon\rho_\infty(v, \{v_i\}) &= (\sqrt{\bar{x}^2 - \frac{1}{2}})^2 + \epsilon \sum_{i=0}^{\infty} \frac{1}{(i+1)}(i+1)\rho(\omega(v, v_i)) \\ &\leq \bar{x}^2 - \frac{1}{2} + \frac{1}{2} = f(\bar{x}). \end{aligned}$$

Let $\tilde{f} := f + \epsilon\rho_\infty$. For every $\bar{x} \in X$, we get

$$f(v) + \epsilon\rho_\infty(v, \{v_i\}) \leq f(\bar{x}) + \epsilon\rho_\infty(\bar{x}, \{v_i\}). \tag{34}$$

Thus $\inf_X \tilde{f} = \tilde{f}(v)$. From (34), we obtain that for any $x \in X$ with $x \neq v$,

$$\begin{aligned} f(v) &< f(x) + \epsilon[\rho_\infty(x, \{v_i\}) - \rho_\infty(v, \{v_i\})] \\ &= f(x) + \epsilon \sum_{i=0}^{\infty} \mu_i(i+1)(\omega(x, v_i) - \omega(v, v_i)) \\ &= f(x) + \epsilon \sum_{i=0}^{\infty} \mu_i(i+1)(\mid\mid x \mid -v_i \mid - \mid\mid v \mid -v_i \mid) \\ &\leq f(x) + \epsilon \sum_{i=0}^{\infty} \mu_i(i+1) \mid\mid x \mid -v \mid \\ &= f(x) + \epsilon \sum_{i=0}^{\infty} \mu_i(i+1)\omega(x, v). \end{aligned} \tag{35}$$

Since $\lim_{i\to\infty} \tilde{f}(v_i) = f(v)$ and inequality (35), it follows that $\tilde{f}(v_i)$ converges to $\tilde{f}(v)$ as $i \to \infty$. By Theorem 3, we have $v_i \to v$ as $i \to \infty$. Hence, we can conclude that a point v is a strong minimizer of $\tilde{f}$. In particular case, if there exists $N \in \mathbb{N}$ such that $\mu_i = 0$ for all $i \geq N$, then

$$\begin{aligned} f(v) + \epsilon \sum_{i=0}^{N-1} \mu_i(i+1)\rho(\omega(v, v_i)) &= (\sqrt{\bar{x}^2 - \frac{1}{2}})^2 + \epsilon \sum_{i=0}^{N-1} \frac{1}{(i+1)}(i+1)\rho(\omega(v, v_i)) \\ &\leq \bar{x}^2 - \frac{1}{2} + \frac{1}{2} = f(\bar{x}). \end{aligned}$$

and v is a strong minimizer of $f + \epsilon\rho_{N-1}$ on X.

 ISBN: 978-84-617-8694-7

Remark 3.5 In the result of Theorem 3.1, it can cover the Borwein-Preiss smooth $\epsilon-$variational principle in [10] by setting

$$p \geq 1,\ \epsilon := \frac{\epsilon}{\lambda^p},\quad \mu_i := \frac{1}{2^{i+1}(i+1)}\quad and\quad \rho(\omega(a,b)) := \omega(a,b)^p \tag{36}$$

with $\omega(x,x) = 0$.

The next corollary gives some direct consequences of the result of Theorem 3.1 when there exists $N \in \mathbb{N}$ such that $\bar{\mu}_i = 0$ for any $i \geq N$

Corollary 3.6 Suppose all the assumptions of Theorem 3.1 and (36) are satisfied. Then there exist v and $\{v_i\}_{i=0}^{\infty}$ are a point and a sequence guaranteed by Theorem 3.1 such that

$$f(v) + \frac{\epsilon}{\lambda^p} \oplus_p (v) \leq f(\bar{x}) \tag{37}$$

and

$$f(v) + \frac{\epsilon}{\lambda^p} \oplus_p (v) < f(x) + \frac{\epsilon}{\lambda^p} \oplus_p (x), \quad \forall\, x \in X \setminus \{v\}, \tag{38}$$

where $\oplus_p(x) = \sum_{i=0}^{N-1} \frac{1}{2^{i+1}}\omega(x,v_i)^p$ and $\omega(x,x) = 0$.

Remark 3.7 Applying the result of Theorem 3.1 by setting

$$\epsilon := \frac{\epsilon}{\lambda},\ \rho(\omega(a,b)) := \omega(a,b),\ and\ \ \mu_i := \frac{1}{2^{i+1}(i+1)}. \tag{39}$$

Looking at the result of Theorem 3.1 (If v is a strong minimizer of $f + \epsilon\rho_\infty$ on X, then v is a strict minimizer of $f + \epsilon\rho_\infty$ on X), we get that for every $x \neq v$

$$\begin{aligned} f(v) &< f(x) + \epsilon[\rho_\infty(x,\{v_i\}) - \rho_\infty(v,\{v_i\})] \\ &= f(x) + \frac{\epsilon}{\lambda}\sum_{i=0}^{\infty}\frac{1}{2^{i+1}}(\omega(x,v_i) - \omega(v,v_i)) \\ &\leq f(x) + \frac{\epsilon}{\lambda}(|\ x - v_i\ | - |\ v - v_i\ |) \\ &\leq f(x) + \frac{\epsilon}{\lambda}(|\ x - v\ |) \\ &= f(x) + \frac{\epsilon}{\lambda}\omega(x,v). \end{aligned} \tag{40}$$

For any sequence v_i satisfying $\lim_{i\to\infty}(f(v_i) + \frac{\epsilon}{\lambda}\omega(v,v_i)) = f(v)$ and inequality (40), it implies that $f(v_i) + \epsilon\rho_\infty(v_i,\{v_i\}) \to f(v) + \epsilon\rho_\infty(v,\{v_i\})$ as $i \to \infty$. By Theorem 3.1, we have $v_i \to v$ as $i \to \infty$. Therefore, v is a strong minimizer for $f + \frac{\epsilon}{\lambda}\omega(\cdot,v)$.

We can establish a corollary which extends and strengthens a result of Georgiev in a complete metric space [6].

Corollary 3.8 Let (X,d) be a complete metric space, $f : X \to \mathbb{R} \cup \{+\infty\}$ be a lower semicontinuous bounded below, $\epsilon > 0$, and $z \in X$. Suppose that

$$f(z) < \inf_{\bar{x}\in X} f(\bar{x}) + \epsilon.$$

 ISBN: 978-84-617-8694-7

Then for every $\lambda > 0$, there exists $v \in \mathbf{B}_\lambda(z)$ is a strong minimizer for the function $x \mapsto f(x) + \frac{\epsilon}{\lambda}\omega(x, v)$.

Acknowledgments The authors would like to thank Naresuan University and King Mongkut's University of Technology North Bangkok. We thank the anonymous referee for the careful reading of the paper and a valuable suggestion improving the presentation.

Abstract

Polyhedron representation is widely used in the field of static analysis by abstract interpretation, to express the invariant of program. These invariants are used to verify the safety of programs. The used of the polyhedron invariant makes the analysis very expressiveness but also very time consuming. The idea is to find a good trade off between the expressiveness and the time execution. For that, we propose in this article an optimisation method to over-approximate the polyhedron invariant by minimizing the loss of precision.

Key words: Optimisation problem, Polyhedral representation, Static Analysis.

1 Introduction

Static analysis aims at automatically analysing computer program behaviours, without actually executing programs. As a representative example, the numerical safety of a program can be verified by computing the set of values that the variables of the program can reach during its execution, taking into account all possible program inputs. The set is known as the *invariant* of the program. The goal is to be able to declare at the end of the analysis **that nothing bad, caused by the numerical variables, will happen**, like for example **No division by zero** or also **No overflow**.

Abstract interpretation is a widely-used and efficient approach in static analysis. The main advantage of this approach lies in the fact that it allows designing sound static analyser based on the notion of *abstract domains*. The latter can be seen as a mathematical representation of the program behaviours, which must be easily manipulated and stored in

 ISBN: 978-84-617-8694-7

computer memory. Once the type of the abstract domains is fixed, a sequence of (abstract) semantics is used to interprete the program. The semantics must be chosen in accordance with the abstract domains in order to easily manipulate them. The program behaviour, i.e., the set of values that all the program variables can possibly reach, can then be over-approximated by the least fixed-point of the monotone map on the abstract domain defined by the (abstract) semantics of the program [5, 3]. Using Tarski's theorem [15], this fixed-point can be computed as the limit of the iterates of the monotone map starting from the least element.

Unfortunately, due to the over-approximation, an affirmative answer to the numerical safety is not always possible because the over-approximation can possibly add some false alarms. Therefore, in the case where the static analysis returns bugs, it is impossible to know if these bugs are false alarms or not. So, the analysis answer will **be We don't know**. The important point to note here is that the quality of the analysis depends on the quality of the chosen abstract domain. However, the quality of an abstract domain is defined by two parameters: the amount of approximation added to the corresponding concrete element and the efficiency of its operators (the semantics). In other words, this quality is controlled by both the complexity and accuracy of the computation.

A common example of abstract domain is a polyhedral over-approximation of the set of values that program variables can take. For example, the abstract domain of a one-variable (x) program can be an interval $[\min x, \max x]$ where $\min x$ ($\max x$) is the minimal (maximal) value that the variable x can take, though not all the values in $[\min x, \max x]$ are reached in the program. More generally, polyhedron abstract domain [4] is defined by a conjunction of linear constraints of the form

$$\bigcap_{i=1}^{m} \{x \in \mathbb{R}^n : \langle a_i, x\rangle \leqslant b_i\}, \tag{1}$$

where $\langle \cdot, \cdot \rangle$ denotes the standard inner product, $x \in \mathbb{R}^n$ represents the n variables of the program and $\{a_1, \cdots, a_m\} \subset \mathbb{R}^n$ and $\{b_1, \cdots, b_m\}$ fully define the abstract domain.

On one hand, the polyhedral abstract domain returns invariants which express a large set of properties. On the other hand, this expressiveness makes the analysis more complex and expensive: it has worst-case exponential space and time complexity. A lot of efforts have been made to find a good trade-off between expressiveness and efficiency. In [2], a fast version of the polyhedral abstract domain is defined, to decrease the complexity of the analysis. A decomposed version of the polyhedron in used instead of the complete one.
To reduce the expressiveness of the analysis new domains have been developed, which allow to express only a certain kind of linear relations between variables. These domains are known as the weakly relational abstract domains [8, 10, 12, 7, 14]: for example, the octagon abstract domain [10] encodes relations of the form $\pm x \pm y \leqslant c$ for $c \in \mathbb{R}$. In [14], authors define an abstract domain based on supporting functions. The corresponding analysis uses templates,

 ISBN: 978-84-617-8694-7

which represent a set of directions uniformly distributed on the unit sphere. More precisely, the vectors $\{a_i\}$ in (1) are chosen from the unit sphere and the scalars $\{b_i\}$ are determined by the analysis. Indeed, the analysis in [14] computes the templates abstraction of the least fixed point obtained using the polyhedral analysis, which means that the accuracy of this analysis depends strongly on the chosen templates. The authors in [13] propose a novel technique to define a relevant template using the principal components analysis. They combine this technique with the abstract domain defined in [14] to improve its accuracy. To be efficient, the cardinality of the obtained template should be as big as possible. The bottleneck is that the number of constraints m can be so large that the computation and analysis of the resulting polyhedron (1) can be very expensive. Moreover, the number of the linear constraints increases during the analysis, while a minimal representation should be maintained to perform the analysis. For that, the redundancy of each constraint is checked by solving a linear programming problem, which makes the analysis very time consuming. In [9], authors present method to decrease the complexity of the redundancies elimination process by reducing the number of LP problem solved. For that, the method of raytracing is used.

In this paper, we propose a method to reduce the number of linear constraints used to describe the polyhedron while trying to minimize the loss of accuracy. More precisely, given a polyhedral invariant in the form of (1), we want to find $\{i_1, \cdots, i_k\} \subset \{1, \cdots, m\}$ to over-approximate the polyhedral invariant (1) as follows:

$$\bigcap_{i=1}^{m} \{x \in \mathbb{R}^n : \langle a_i, x\rangle \leqslant b_i\} \simeq \bigcap_{j=1}^{k} \{x \in \mathbb{R}^n : \langle a_{i_j}, x\rangle \leqslant b_{i_j}\}. \tag{2}$$

Here k is a number smaller than m. In principle it should be chosen in accordance with the memory limit. The idea is to delete those constraints which constribute the least to the computation of the polyhedron. For this purpose, we randomly generate witness points on the boundary of the polyhedron and define distance functions between the witness points and the halfspaces $\{x \in \mathbb{R}^n : \langle a_i, x\rangle \leqslant b_i\}$. We then formulate a k-median problem, where k is the number of inequalities that we want to maintain, and solve the k-median problem by Jain and Vazirani's approximation algorithm. The output of the optimization algorithm is directly related to k halfspaces, the intersection of which is the overapproximation of the original polyhedron. Afterwards, this method is used as a substitution method of the redundancies elimination process in the case of static analysis by abstract interpretation, to increase its efficiency.

 ISBN: 978-84-617-8694-7

2 Polyhedron over-approximation

2.1 Problem formulation

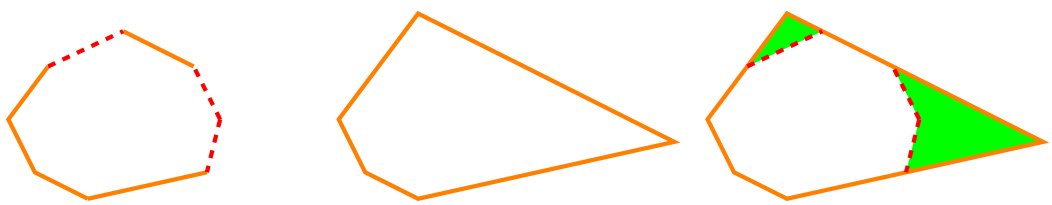
Let $\{a_1, \ldots, a_m\} \subset \mathbb{R}^n$, $\{b_1, \ldots, b_m\} \subset \mathbb{R}$ and $P \subset \mathbb{R}^n$ be the polyhedron defined as the intersection of m halfspaces:

$$P := \bigcap_{i=1}^{m} \{x \in \mathbb{R}^n : \langle a_i, x\rangle \leqslant b_i\}, \tag{3}$$

where $\langle \cdot, \cdot \rangle$ denotes the standard inner product in Euclidean space. We assume throughout the paper that P is bounded and has nonempty interior. In addition, we assume that $\|a_i\| := \sqrt{\langle a_i, a_i\rangle} = 1$ for all $i \in [m]$. Fix some $k \in [m] := \{1, \cdots, m\}$. Let $S \subset [m]$ be a subset of cardinality k. Associated with S we define a new polyhedron $Q(S)$:

$$Q(S) := \bigcap_{i \in S} \{x \in \mathbb{R}^n : \langle a_i, x\rangle \leqslant b_i\}, \tag{4}$$

obtained by removing all the linear constraints not in S. Then $Q(S)$ gives an overapproximation of P, defined as the intersection of k halfspaces. We give a simple illustration in Figure 2.1. The polytope $Q(S)$ shown in Figure 1(b) is obtained by removing the three dashed faces of the polygon P given in Figure 1(a).



(a) Polygon P (b) Polygon $Q(S)$ (c) Polygon $Q(S)$

Figure 1: Example

The approximation error can be measured through the volume difference between $Q(S)$ and P. More precisely, let $\mathrm{vol}(A)$ denote the volume of a polyhedron A, then the volume difference between $Q(S)$ and P is given by $\mathrm{vol}(Q(S)) - \mathrm{vol}(P)$. In the example of Figure 2.1, the volume difference between the polygon $Q(S)$ and P is the volume of the region filled in green in Figure 1(c). Given two subsets S_1 and S_2 of cardinality k, $Q(S_1)$ is preferrable to $Q(S_2)$ if $\mathrm{vol}(Q(S_1)) \leqslant \mathrm{vol}(Q(S_2))$. The "best" approximation of P is then the polyhedron with minimum volume associated with a subset with cardinality k. In other words, we need to solve the following combinatorial optimization problem:

$$\min_{\substack{S \subset [m] \\ |S| = k}} \mathrm{vol}(Q(S)) - \mathrm{vol}(P). \tag{5}$$

 ISBN: 978-84-617-8694-7

Although the solution of optimization problem (5) returns the best overapproximation in terms of minimum volume difference, we will not attempt to solve it directly. In fact, even the volume computation is known to be a #-complete problem [6]. Instead, we will formulate in the following a discrete approximation of (5), which can be solved to some extent by polynomial-time algorithms.

2.2 Distance functions

For each $j \in [m]$ we define the hyperplane

$$H_j := \{x \in \mathbb{R}^n : \langle a_j, x\rangle = b_j\}.$$

The boundary of P is the set of points in P which intersect with at least one hyperplane, i.e.,

$$\mathrm{bd}(P) = \bigcup_{i=1}^{m} \left(P \bigcap H_i\right).$$

For any $x \in \mathrm{bd}(P)$ and $j \in [m]$, define the projection operator:

$$\Pi_j(x) := \arg\min\{\|x - y\| : y \in H_j\}.$$

That is, $\Pi_j(x)$ is the point on the hyperplane H_j which is closest to x. Now we define the projective distance of x to the hyperplane H_j as follows:

$$p_j(x) := \|x - \Pi_j(x)\|.$$

It is easy to check that:

$$p_j(x) = b_j - \langle a_j, x\rangle, \;\; j \in [m], x \in \mathrm{bd}(P).$$

The relative interior of $\mathrm{bd}(P)$ is the set of points in P which intersects with exactly one hyperplane, i.e.,

$$\mathrm{ri}(\mathrm{bd}(P)) = \bigcup_{i=1}^{m} \left(P \bigcap H_i \backslash \left(\bigcup_{j \neq i} H_j \right) \right).$$

Therefore, for $x \in \mathrm{ri}(\mathrm{bd}(P))$, there is a unique index $i \in [m]$ such that $x \in H_i$. For any $j \in [m]$, we then define the inverse projection operator as follows:

$$\Pi_j^{-1}(x) := \{y \in H_j : \Pi_i(y) = x\}.$$

That is, $\Pi_j^{-1}(x)$ is the point in H_j whose projection onto the hyperplane H_i is x. For any $x \in \mathrm{ri}(\mathrm{bd}(P))$ and $j \in [m]$, we define the inverse projective distance $\delta_j(x)$ as follows.

$$\delta_j(x) := \|x - \Pi_j^{-1}(x)\|.$$

 ISBN: 978-84-617-8694-7

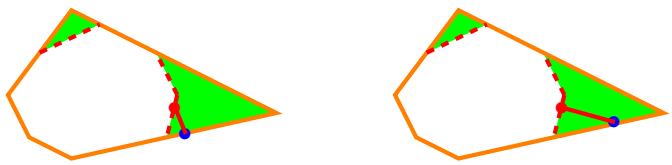
It can be checked that:

$$\delta_j(x) := \frac{b_j - \langle a_j, x\rangle}{\max\left(\langle a_i, a_j\rangle, 0\right)}, \quad j \in [m], x \in \mathrm{ri}(\mathrm{bd}(P)) \cap H_i. \tag{6}$$

Since $\|a_i\| = 1$ for any $i \in [m]$, we clearly have

$$\delta_j(x) \geqslant p_j(x) \geqslant 0, \quad \forall x \in \mathrm{ri}(\mathrm{bd}(P)), \quad j \in [m]. \tag{7}$$

In Figure 2.2 we give an illustration of the projective distance $p.(\cdot)$ and the inverse projective distance $\delta.(\cdot)$. Note that the blue point in Figure 2(a) is the projection of the red point onto the hyperplane which contains the blue point. The red point in Figure 2(b) is the projection of the blue point onto the hyperplane which contains the red point.



(a) blue=Π_j(red) (b) blue=Π_j^{-1}(red)

Figure 2: Illustration of projection and inverse projection operators.

2.3 Volume difference approximation

The normal cone to P at $x \in P$ can be written as [11, Theorem 6.14]:

$$N_P(x) = \left\{ \sum_{i=1}^{m} y_i a_i : y_i \geqslant 0, y_i(\langle a_i, x\rangle - b_i) = 0, \quad \forall i \in [m] \right\}. \tag{8}$$

As an illustration, the normal cone of the polygon P in Figure 1(a) is the region filled with blue lines in Figure 3(a). Now define

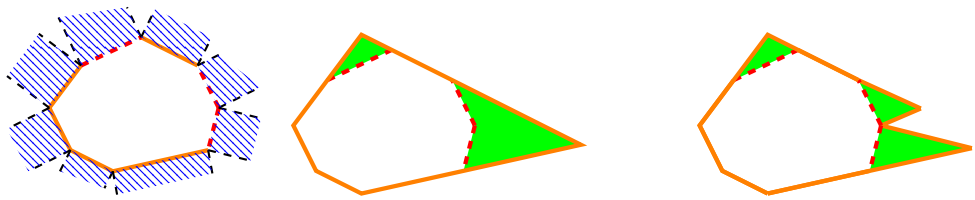
$$O(S) = Q(S) \backslash \left(\bigcup_{x \in \mathcal{F}_{n-2}(P)} \{x + N_P(x)\} \right),$$

where $\mathcal{F}_{n-2}(P)$ denotes the set of faces with dimension $n-2$. We give in Figure 3(c) an illustration of $O(S)$.

Proposition 1. *We have*

$$\mathrm{vol}(O(S) \backslash P) = \int_{\mathrm{ri}(\mathrm{bd}(P))} \min_{j \in S} \delta_j(x) dx \tag{9}$$

 ISBN: 978-84-617-8694-7



(a) $N(P)$ (b) $Q(S)$ (c) $O(S)$

Figure 3: Illustration of the normal cones and $O(S)$.

Remark 1. *The integration in* (9) *can be decomposed into the sum of integrations over faces of* P*, each of which is reduced to a standard integration on a compact domain in* $\mathbb{R}^{n-1}$*.*

The proof of Proposition 1 is omitted due to the page limit. We propose to approximate problem (5) as follows:

$$\min_{\substack{S\subset[m]\\|S|=k}} \int_{\mathrm{bd}(P)} \min_{j\in S} d(j,x)dx \tag{10}$$

where the integral $d(j,x)$ can be replaced by the projective distance $p_j(x)$ or the inverse projective distance $\delta_j(x)$. Note that by (7), we have:

$$\int_{\mathrm{bd}(P)} \min_{j\in S} p_j(x)dx \leqslant \int_{\mathrm{ri}(\mathrm{bd}(P))} \min_{j\in S} \delta_j(x)dx \leqslant \mathrm{vol}(Q(S)\backslash P). \tag{11}$$

2.4 Integration approximation

To obtain an approximation of the integration in (10), we propose to generate a discrete set X of "representative" points and approximate as follows:

$$\sum_{x\in X} \min_{j\in[m]} d_j(x) \simeq \int_{\mathrm{bd}(P)} \min_{j\in[m]} d_j(x) \tag{12}$$

A natural choice of X appears to be a subset of points uniformly distributed over $\mathrm{bd}(P)$. For this purpose, we apply the *running shake and bake* algorithm introduced in [1].

2.5 k-median problem

Let X be a discrete subset of P and $d(\cdot,\cdot) : [m] \times \mathbb{R}^n \to \mathbb{R}_+$ be a distance function. We propose to solve the following discrete approximation problem of (5).

$$\min_{\substack{S\subset[m]\\|S|=k}} \sum_{x\in X} \min_{j\in S} d(j,x). \tag{13}$$

 ISBN: 978-84-617-8694-7

In view of the previous discussion, we know that if X approximates the uniform distribution over $\mathrm{bd}(P)$ and $d(\cdot,\cdot)$ is either the projection distance $p_\cdot(\cdot)$ or the inverse projection distance $\delta_\cdot(\cdot)$, then (13) provides an approximation of the original problem (5).

We recognize in (13) the k-median problem. Indeed, here we identify the discrete set X as cities and the hyperplanes $H_1, \cdots, H_m$ as facilities and the distance between a city $x \in X$ and a facility H_j is $d(j, x)$. We then apply the algorithm of Jain and Vazirani , designed for approximately solving k-median problems in polynomial time.

3 Numerical Experiments

To show the efficiency of our optimisation method, we use it in the field of static analysis by abstract interpretation to improve the analysis process. Especially, when the analysis is performed using the polyhedra abstract domain, this is known as the polyhedral analysis. Our optimisation method is applied to decrease the complexity of the polyhedral analysis, by over-approximating the obtained polyhedron fixed-point.

We include the optimisation method in our static analyser, then we apply it to analyse several programs. The used programs contain a number of stable linear systems and digital filters, known to be hard to analyse using the polyhedral analysis. The experimentations are done on $2.4GH_Z$ Intel Core2 Duo laptop, with $8Gb$ of RAM. To show the quality of the obtained over-approximation, we used Matlab [1] to compute the volume of the obtained polyhedra. The results are summarised in Table 1. Table 1 shows the volume of the initial polyhedron, it is the polyhedron obtained using the polyhedral analysis. The volume of the over-approximated polyhedron is given using two metrics the projective distance and the inverse projective one. It is the polyhedron obtained using the polyhedral analysis mixed with the optimisation method. Note that, N represents the number of constraints of the initial polyhedron. And $K \leqslant N$ is the number of constraints of the over-approximated polyhedron. We have also that $|V|$ is the number of programs variables, we use its to show the scalability of our method. The results of Table 1 show that the optimisation method, in the most of cases, does not add a big amount of over-approximation. To illustrate the precision of our analysis, we display on Figure 4 and Figure 5 the result given in Table 1 for, respectively, the example `filter2` and `Harmonic_oscillator`. Note that, figures are given in dimension 2. The results of the polyhedral analysis, given by the red polyhedra, and the one obtained using the polyhedral analysis with the optimisation method, is given by the blue polyhedra. Note that, the red polyhedra are contained into the blue polyhedra, this shows the quality of the invariant we compute.

Acceptance Tail Method for Sampling from Unimodal Distributions

Efraim Shmerling[1]

[1] *Department Mathematics, Ariel University,Science Park,44837 Ariel,Israel*

emails: efraimsh@ariel.ac.il

Abstract

A universal method for generating continuous random variables (rv's) with unbounded range and infinite-valued discrete rv's is presented.The validity of the method is proved . It is shown in some detail how the method can be implemented for generating unimodal continuous rv's. Theorem that enables one estimate the efficiency of the unimodal version of the presented method is formulated.

Key words: random veriable generation,ziggurat algorithm, unimodal distribution

1 Introduction

A new efficient method named acceptance tail (AT) for generating rv's is presented in the paper. Different versions of the AT method have been developed: a discrete version, a multivariate continuous version, a multimodal univariate continuous version and the univariate unimodal continuous version which will be called the $UMAT$ method in further discussion. The development of these versions shows that the AT method like the "classical" acceptance rejection (AR) method extends to all types of rv's except multivariate rv's of high order. In Section 2 the general AT method is presented. In Section 3 which is the most important part of the paper the $UMAT$ method is described in some detail. For the case where the probability density function (pdf) is monotonically decreaing or is a symmetric unimodal function, a very efficient in terms of generation time ziggurat algorithm has been developed by Marsaglia and Tsang (see [1,2]), and became the standard generator for Gaussian rv's in many platforms. However the ziggurat algorithm has not been implemented for distributions other than Gaussian and exponential, primarily due to complicated and time-expensive setup and the fact that is does not extend to nonmonotonic and nonsymmetric

 ISBN: 978-84-617-8694-7

distributions. In section 3 of the paper it is shown how the presented UMAT method overcomes these drawbacks of the ziggurat algorithm while retaining its main advantage which is high computational speed.

2 DESCRIPTION OF THE GENERAL AT METHOD

In order to describe the general AT method we introduce the following notations. Let X designate the "target" rv . Let the term: "density region" denote in the case where X is a continuous rv the region under the graph of the pdf f(x) of X , and the union of vertical intervals which extend from $(x_i; 0)$ to $(x_i; p(x_i)), x_i \in R, i = \overline{1, \infty}$ in the case where X is a discrete rv. Here p(x) designates the probability mass function of X. Let H designate in the case where X is a continuous rv a bounded part of R such that the integral $\int_H f(x)dx = 1-\delta$ is very close to one , and in the discrete case a finite subset of R such that the sum

$$\sum_{i:x_i \in H} p(x_i)$$

is very close to one. Let T designate the complement of R with respect to H. Let C designate the "head" of the density region which is the part of the density region over H, and let D designate the "tail" of the density region which is the part of the density region over T. Let V(A) designate the volume of a domain A in the case where $A \subset R^k, k \geq 2$, square of A in the case where $A \subset R^2$, and the total length of the "vertical" intervals included in A in the case where A is a union of "vertical" intervals.

The AT method is based on covering C by a set of m instrumental units L_i, $1 \leq i \leq m$ which are "vertical" intervals with common length $1/n$ in the discrete case, rectangles with common area $1/n$ in the univariate continuous case or hyperrectangles with common volume $1/n$ in the multivariate case, $n \geq m$. An algorithm for defining the instrumental units is a part of any specific version of the AT method. Besides defining the set of instrumental units, an algorithm for generating the "tail" rv G needs to be chosen at the preliminary stage of AT. The pdf $g(x)$ of G is defined by the formula: $g(x) = f(x)/\delta$, $x \in T$ in the case where X is continuous, and the pmf $g(x)$ of G is defined by the formula : $g(x_i) = p(x_i)/\delta$, $x_i \in T$ for the case where X is discrete. Note that the efficiency of the algorithm for generating G does not affect significantly the efficiency of the AT method since the probability that the generation of G will be required in order to obtain a generated value of X is very low as shown below. In order to define the set of instrumental units respective tables need to be initialized at the setup stage of the AT method. Provided that such tables have been initialized and the algorithm for generating G chosen, the generation of X looks as follows.

1. Select randomly an integer i in the range $1 : n$ (thus one of the covering elements L_i is chosen).

 ISBN: 978-84-617-8694-7

2. If $i \leq m$, generate a point $P = (P1; P2)$ uniformly distributed in L_i; otherwise go to step 4.

3. If P belongs to the density region of X, set $X = P1$.

4. Generate G and set $X = G$.

Obviously, by the presented method a point P is chosen from the density region of X and $P1$ accepted as a generated value of X. (At step 4 a point P is selected from D by the AR method, and P1 is accepted as a generated value of X). Thus in order to prove the validity of the AT method it is enough to show that for any domain A which belongs to the density region of X the probability P(A) that the selected by the AT method point P belongs to A equals V(A). In order ro prove the assertion, let's first consider the case where

$$A \subset \widehat{L_i} = L_i \bigcap C, 1 \leq i \leq m$$

for some $i, 1 \leq i \leq m$. In this case we have

$$P(A) = P(B_i) * P(A|B_i) = (1/n) * (V(A)/(1/n)) = V(A),$$

where the event B_i is selecting the integer i at step 1. Now let's consider the case where $A \subset D$. In this case in order to show that $P(A) = V(A)$ it is enough to show that the probability $P(D)$ that step 4 will be executed in generating a sampled value of X by the AT method equals $V(D) = q$. Obviously, P(D) can be expressed as the sum $(n-m)/n + \sum_1^m P_i(D)$, where the first term is the probability that an integer larger than m will be chosen at step 1, and $P_i(D)$ is the probability that a given integer i less or equal to m will be chosen at step 1 and the point P generated at step 2 will not belong to $\widehat{L_i}$. The probability $P_i(D)$ equals $(1/n) * ((1/n - V(\widehat{L_i}))/(1/n)) = 1/n - V(\widehat{L_i})$. It follows that the sum $\sum_1^m P_i(D)$ equals $\sum_1^m (\frac{1}{n} - V(\widehat{L_i})) = \frac{m}{n} - \sum_1^m V(\widehat{L_i}) = \frac{m}{n} - V(C) = \frac{m}{n} - (1-q)$, therefore P(A)=P(D). Q. E. D.

3 THE UNIVARIATE UNIMODAL VERSION OF THE AT METHOD

Let's consider the case where the pdf $f(x)$ of the "target" rv X is monotonically decreasing with mode $M = 0$. n horizontal rectangular layers $L_i, 1 \leq i \leq n$ with common area $1/n$ need to be obtained according to the procedure described below, a layer i extends from 0 to x_i horizontally and from y_i to y_{i-1} vertically, $x_0 = 0, y_0 = f(0), x_{1-1} \leq x_i, y_i < y_{i-1}, 1 \leq i \leq n$. The obtained instrumental units define H as $H = \{x : 0 \leq x \leq x_n\}$.

At the setup stage of the $UMAT$ method 2 tables: $\{x_i\}_{i=1}^n, \{y_i\}_{i=1}^n$ have to be generated. Let G designate the "tail" rv with pdf $g(x) = f(x)/\delta, x > x_n$. Then the generation stage of the $UMAT$ method looks as follows.

 ISBN: 978-84-617-8694-7

1. Select randomly an integer i in the range $1 : n$.
2. Generate U_0 uniformly distributed in $(0, 1)$ and calculate $s = U_0 * x_i$.
3. If $s < x_i$, set $X = s$.
4. Generate U_1 uniformly distributed in $(0, 1)$ independently of U_0.
5. If $U_1 < (f(s) - y_i)/(y_{i-1} - y_i)$, set $X = s$;
6. generate G and set $X = G$.

The initialization of the tables required by the $UMAT$ method looks as follows. First the values of $x_i\,, y_i\; i = 1, 2, ...$ are calculated recursively utilizing the equalities:

$$(f(x) - y_{i-1}) \cdot x_i = \frac{1}{n},\; y_i = f(x_i),\; x_0 = 0,\; y_0 = f(0). \tag{1}$$

The consecutive values of x_i are calculated until the point x_{i^*}, for which the condition $S(i^*) = \sum_{j=1}^{i^*}(x_j - x_{j-1}) \cdot f(x_{j-1}) > 1$ is satisfied, is obtained. Since $S(i^* - 1) < 1$ and $S(i^*) > 1$, the following inequality holds: $x_{i^*-1} < d = (n - i^* + 1)/(n \cdot f(x_{i^*-1})) < x_{i^*}$. We set $x_i = d, i^* \le i \le n$, and we set $y_i = f(x_i), 1 \le i < i^*$, $y_i = f(x_{i^*-1}/(n-i^*+1) \cdot (n-i), i^* \le i \le n$.

Note that the generation of the tables requires calculating a root of the equation (1) less than n times. Ziggurat method requires the calculation of the common area A of the layers utilizing an iteration method (such as the bisection method), and at each iteration the equation $f(x) = y_i$, where $y_i = y_{i-1} + A/x_{i-1}$ has to be solved for each i, $1 < i \le n$, i. e. $n - 1$ times, from which follows that the setup time required by the $UMAT$ method is many times shorter than the setup time of the ziggurat. The main advantage of the $UMAT$ method is its computational speed which follows from the fact that the probability $P^*(n)$ that only the first 3 steps of the algorithm will be executed in order to obtain a generated value of the "target" rv X is close to one for sufficiently large n. In order to estimate $P^*(n)$ we introduce the following notation. Let $E_i, 1 \le i \le i^*$ designate the rectangular part of L_i bounded on the left by the line $x = x_i$, and let $S(A)$ designate the area of an arbitrary region A in R^2. Then $P^*(n)$ can be calculated via the following formula: $P^*(n) = 1 - S(U_2^{i^*} E_i) - 1/n$. The following theorem proves that $P^*(n)$ tends to one as n tends to infinity and enables one to estimate the rate of convegence.

Theorem 1

If the derivative of $f(x)$ is bounded : $\mid f^{'}(x) \mid \le M, x > 0$, then for any $\delta > 0$ and any n which satisfies the inequality

$$\frac{2.5 + ln(\sqrt{Mn} \cdot x_\delta)}{n} < \delta$$

 ISBN: 978-84-617-8694-7

the following inequalities hold: $x_n > x_\delta$ and $S(U_1^{i^*} E_i) < 2\delta$. Here x_δ desinates the point on the x-axis for which the equality $\int_{x_\delta}^{\infty} f(x)dx = \delta$ is satisfied.

Utilizing the theorem, the proof of which will be presented in the full version of the paper, we have shown that for gamma distributions and many other widely used distributions the rate of convergence of $P^*(n)$ to one with growth of n is very high, therefore the UMAT method can be implemented very successfully in sampling from these distributions.

Abstract

The incorporation of hydrogen into transport systems means not only the incorporation of vehicles with new technologies, but the creation of a new infrastructure that encompasses production, storage, transport and distribution, spearheaded by the refueling hydrogen stations. For this reason, it is almost essential to develop a methodology for selection and optimized sizing of the logistics associated with hydrogen systems. Given this situation, this study has focused on the need to create a methodology that will help to solve the dimensioning of the hydrogen refueling facilities and the logistics involved.

Key words: Hydrogen, Logistics, Fueling station, Sizing methodology, Optimization

1 Introduction

Transportation is an activity derived from other activities taking place in a given geographical area, a country, a region, a city or a neighborhood [9]. Its most evident manifestation is the urban traffic, that is to say, the people and vehicles circulation by the public spaces of the city. Starting from this definition, a series of determinants are presented as responsible for the evolution that has led to the urban transport to the point of transition in which it is at present. On the one hand, transport has to adapt to the available resources and the topology of cities, but also to a series of problems that are the result of uncontrolled growth; congestion, pollution and limitation of available resources makes inevitably the need for new alternative transport systems [1].

The incorporation of hydrogen into transport systems means not only the incorporation of vehicles with new technologies, but the creation of a new infrastructure that encompasses production, storage, transport and distribution, spearheaded by the refueling hydrogen stations. The extent to which emission reduction will occur depends on the mix of technologies that make up the hydrogen supply chain [2, 10, 13]. For this reason, it is almost essential to develop a methodology for selection and optimized sizing of the logistics associated with hydrogen systems at two levels. On the one hand, it is necessary to develop a model that could define the characteristics of hydrogen stations automatically and also in a simple and agile way. On the other hand, it is required a complete simulation model that has as objective the

 ISBN: 978-84-617-8694-7

detailed sizing of the hydrogen stations according to their particularities, and whose functional bases are embodied in this study.

Given this opportunity, the present work presents a methodology that tries to give solution to the sizing of the hydrogen refueling facilities and the logistics involved.

2 Hydrogen refueling facilities

There are different types of hydrogen stations from the point of view of hydrogen supply, taking into account both technical and economic viability of this product. In the future, the location of the hydrogen stations will influence in the technical solution adopted for the supply: hydrogen stations located in remote locations, large stations in rural areas, hydrogen stations located in the environs of the cities or hydrogen stations located in main roads.

3 Methodology

The methodology proposed in this work is formed by:

- A model that defines the characteristics of hydrogen-type stations from an input data and that has been denominated *Pattern of Use*.
- A calculation model that allows the complete sizing of a hydrogen station depending on the particularities of each case.

3.1 Pattern of Use

The Pattern of Use is a model that defines the basic characteristics of a hydrogen-type station from basic input data: the type and the number of vehicles that are expected to be use by the facility. The characteristics it defines are: the number of dispensers required, the daily supply flow, the type of supply and the approximate cost of the infrastructure. In this way, it is obtained a pre-design of the installation that will be used as the first level of the calculation model object of the present study.

After analysing the documentation on the most representative projects and experiences on the subject, there was no shared trend in the structure and technologies of the hydrogen refueling facilities used in these projects [3–8, 11]. In addition, as the vast majority are demonstration projects, these stations are highly oversized, consequently, modelling by means of direct assignment of the type of hydrogen station according to the experience was not advisable.

As a consequence of this previous analysis, a formulation to make the model has been used in order to determine the number of dispensers, the delivery flow, limited by the number of dispensers and an approximate cost, in a generic way.

The objective is to provide a hydrogen station pre-sizing and an approximate cost, as close to reality as possible, starting from a single initial data, which are the vehicles (buses and passenger cars) that are expected to use the facilities on a daily basis.

As a prerequisite to perform the calculations, it is needed to know:

- The average capacity of hydrogen deposits with which the vehicles count.
- The different models, both electrolyzers and reformers.
- The estimated time that the hydrogen production equipment can remain in operation.

 ISBN: 978-84-617-8694-7

- The characteristics of the hydrogen delivery process of the dispenser. It is especially important the rate at which hydrogen is supplied.
- The hours in which the station remains operational.
- The time it takes to perform the refueling ($T_{refueling}$) of a vehicle and which is calculated by the following formulas:

$$T_{refueling}(min) = T_{approximation}(min) + T_{preparation}(min) + T_{exit}(min) + T_{supply}(min) \quad (1)$$

$$T_{supply}(min) = T_{unitary}(min/(kgH_2)) * Tank\_Capacity(kgH_2) \quad (2)$$

The starting data to be taken into account in the model are as follows: Propulsion; Number of vehicles; Number of dispensers; Refueling capacity; Type of supplying; In situ supply amount; Exterior supply amount; Storage capacity; Costs.

3.2 Calculation Model

The calculation model will allow to determine what should be the main characteristics that a hydrogen supply station has to face, depending on the needs to cover and the external conditions that surround it. The purpose of the calculation model is to achieve a criterion that allows the sizing and the correct placing of a hydrogen supply station, taking into account economic, technical and environmental aspects.

The global process of development of the calculation model is divided into four phases, each of them subdivided into several activities: Analysis of requirements and specifications of the calculation model; Design of the calculation model; Validation of the calculation model; Feedback of the calculation model.

To facilitate the compression of the operation of this model, Figure 1 shows the general scheme of the calculation model, which helps to understand the mechanism used to decide the configuration of the hydrogen station infrastructure. This modeling allows to know the environment and particularities in which the new infrastructure will be located, and will help to determine the size, characteristics and location of hydrogen refueling stations network that minimizes the cost functions and maximizes those of operation and functionality.

Firstly, it is necessary to determine the number of hydrogen stations which is needed to satisfy the total hydrogen demand.

The $Simulation_A$ process takes place if there is no hydrogen station with in situ production or hydrogen production plant near the hydrogen station. In this case, it is simulated that only one production plant will supply the n hydrogen stations, that is, it will take care of the production of all the demand, a result obtained in the process of calculating the number of hydrogen stations. The case of $Simulation_B$, it is studied when there is a hydrogen station plant with in situ production or a production plant near the hydrogen station, but which is not able to supply all the new demand (the total demand calculated in the process of calculating the number of hydrogen stations) plus the previous demand.

Finally, once the simulation process has been completed and the best result has been selected according to the objectives, the last process, called location and adjustment is started. This process is the most complex, since it is necessary to consider a greater number of parameters considering all the alternatives that take place in the previous processes.

In this process, it is firstly determined the location of the in situ production hydrogen stations, and afterwards the distribution ones.

 ISBN: 978-84-617-8694-7

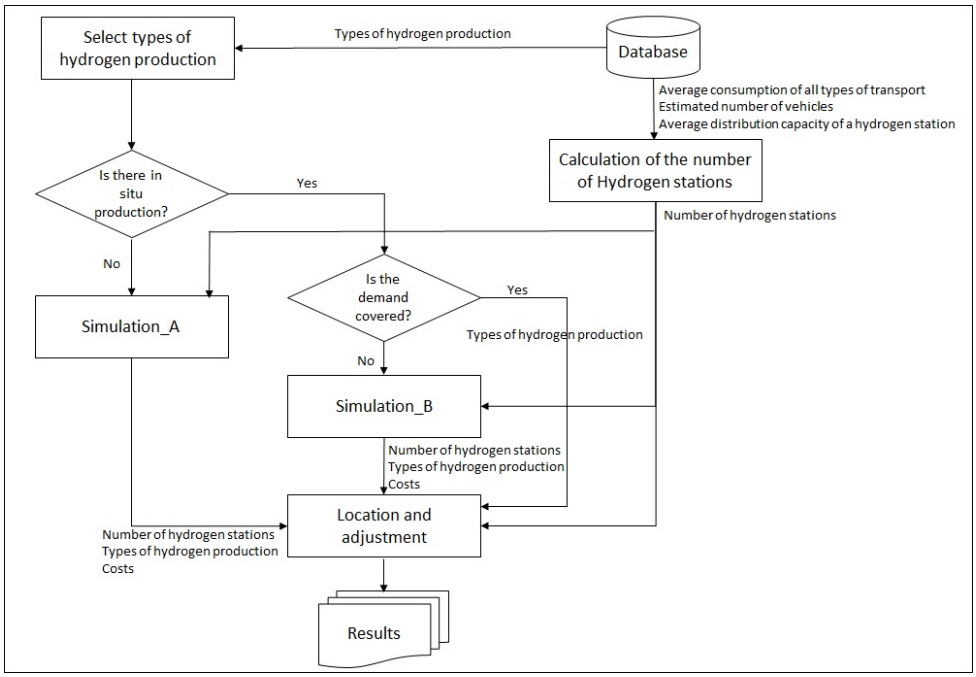

Figure 1: General scheme of a calculation model.

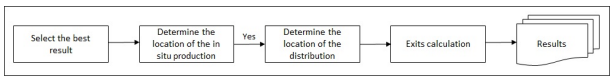

Figure 2: Location and adjustment

4 Conclusions

This study has focused on the need to create a methodology that will help to solve the dimensioning of the hydrogen refueling facilities and the logistics involved. The purpose of the realization of an optimized design of a new distribution infrastructure is to determine the size, characteristics and location of the network of hydrogen refueling stations that minimizes cost functions and maximizes those of operability and functionality.

An essential requirement previous to the determination of the optimum the optimum dimension of the hydrogen refueling stations is the daily hydrogen demand, which will have to be met. This future demand can be determined from demand forecasts of the fleet of public or private vehicles that will use hydrogen in a specific time horizon and the study and design of routes to be followed by vehicles.

When designing the methodology, the point at which it has placed special emphasis, due to its high sensitivity in both the technical and economic aspects, is the type of hydrogen supply to the station. The type of supply depends on four basic variables: cost, demand, location of facilities and security of supply.

Remarks and observations on (q-) Bernstein Basis functions

Yilmaz Simsek[1]

[1] *Department of Mathematics Faculty of Sciences, Akdeniz University*

emails: ysimsek@akdeniz.edu.tr

Abstract

In this paper, we investigate the q-Bernstein bases functions with their generating functions. We give many properties of these functions. We also give recurrence relations and derivative formulas for these functions. Moreover, we give some comments and observations on the q-Bernstein basis functions and the Bernstein basis functions. Finally, we simulate the results by their plots of these functions

Key words: q-Bernstein bases, Generating functions, q-exponential functions, Combinatorial sums.
MSC 2000: 65Qxx, 33Dxx, 65D17, 26Cxx, 30C10.

1 Introduction

The q-calculus related to the q-Bernstein basis functions have many applications in many various different areas. Especially, the Bernstein basis functions are of important role in order to construct the Bézier type curves and their usage are very common in the car design and other relates industrial design and Computer Aided Geometric Design (CAGD). For more detailed information about the properties and their application of the Bernstein basis functions, the reader can consult the following references ([1]-[14]).

Let $x \in [0,1]$. The classical Bernstein basis functions are given by

$$B_k^n(x) = \binom{n}{k} x^k (1-x)^{n-k}, \qquad k = 0, \ldots, n. \tag{1.1}$$

The q-Bernstein basis functions are defined by

$$B_k^n(x;q) = \begin{bmatrix} n \\ k \end{bmatrix}_q x^k \prod_{j=0}^{n-k-1} (1-q^j x), \qquad k = 0, \ldots, n \tag{1.2}$$

where $x \in [0,1]$.

Some q-calculus notations are given as follows:

 ISBN: 978-84-617-8694-7

Let $\begin{bmatrix} n \\ k \end{bmatrix}_q$ denote the q-binomial coefficient defined by

$$\begin{bmatrix} n \\ k \end{bmatrix}_q = \frac{[n]_q!}{[k]_q![n-k]_q!}, \tag{1.3}$$

$k = 0, \ldots, n$, and $q \neq 1$,

$$[k]_q! = [1]_q[2]_q \cdots [k]_q, \tag{1.4}$$

$$[0]_q! := 1,$$

and for $k \in \mathbb{Z}^+$, $[k]_q$ stands for the q-integer given by

$$[k]_q = 1 + q + \cdots + q^{k-1} = \begin{cases} \frac{1-q^k}{1-q}, & q \neq 1, \\ k, & q = 1. \end{cases} \tag{1.5}$$

Relations between $[k]_q$ and $[k]_{1/q}$ are given as follows:

$$[k]_q = q^{k-1}[k]_{1/q} \tag{1.6}$$

and

$$[k]_q! = q^{\binom{k}{2}}[k]_{1/q}!. \tag{1.7}$$

In [3], the q-exponential function $\mathcal{E}_q(x)$ is defined as follows

$$\mathcal{E}_q(x) = \sum_{n=0}^{\infty} \frac{x^n}{[n]_q!}. \tag{1.8}$$

In the work of Goldman et al. [8], we observe that if one uses the ratio test in this series for $\mathcal{E}_q(x)$ converges and therefore $\mathcal{E}_q(x)$ is well defined for all

$$|x| < \frac{1}{|1-q|}$$

if $|q| < 1$, and for all $x \in \mathbb{C}$ if $|q| > 1$ or $q = 1$. Therefore for any fixed value of $q > 0$, there is an interval in which the series for $\mathcal{E}_q(x)$ converges.

By using the q-exponential function $\mathcal{E}_q(x)$, the generating functions for the q-Bernstein basis functions is given by [8]:

$$G_k(x, t; q) = \sum_{n=k}^{\infty} B_k^n(x; q) \frac{t^n}{[n]_q!}, \tag{1.9}$$

where

$$\mathcal{E}_q(xt)G_k(x, t; q) = \frac{(xt)^k}{[k]_q!}\mathcal{E}_q(t).$$

The q-Bernstein operator is given as follows (*cf.* [10]; and also see [9]):

$$B_{n+1,q}(f)(x) = \sum_{k=0}^{n+1} \begin{bmatrix} n+1 \\ k \end{bmatrix} \Delta^k f_0 x^k \tag{1.10}$$

 ISBN: 978-84-617-8694-7

where

$$f_i = f\left(\frac{[i]_q}{[n+1]_q}\right), \Delta^0 f_i = f_i, \Delta^{k+1} f_i = \Delta^k f_{i+1} - q^k \Delta^k f_i,$$

$$\Delta^k f_i = \sum_{j=0}^{k} (-1)^j \, q^{\frac{j(j-1)}{2}} \begin{bmatrix} k \\ j \end{bmatrix}_q f\left(\frac{[i+k-j]_q}{[n+1]_q}\right),$$

and also

$$B_{n,q}(f)(x) = \sum_{i=0}^{n} f\left(\frac{[i]_q}{[n]_q}\right) B_i^n(x;q). \tag{1.11}$$

It is time to give some basic information about the q-calculus.

In [1], [8], the discrete q-derivative of a function $f(x)$ is given as follows: for $q \neq 1$

$$D_{q,x} f(x) = \frac{f(qx) - f(x)}{(q-1)x}.$$

Observe that when $f'(x)$ exists,

$$f'(x) = \lim_{q \to 1} D_{q,x} f(x).$$

The q-integral of a function $f(x)$ is given as follows (*cf.* [1], [8]):

$$\int_0^t f(x) \, d_q x = t(1-q) \sum_{j=0}^{\infty} f(tq^j) q^j, \tag{1.12}$$

provided that the infinite sum converges.

From the above definitions, one can easily get the following formulas:

$$\int_0^t x^n \, d_q x = \frac{t^{n+1}}{[n+1]_q}, \tag{1.13}$$

and

$$\int_0^t x^n \, d_{1/q} x = \frac{t^{n+1}}{[n+1]_{1/q}} = \frac{q^n t^{n+1}}{[n+1]_q}. \tag{1.14}$$

In order to give our results, we need the following Theorems:

Theorem 1.1 (*cf.* [8])**.**

$$\sum_{k=j}^{n} \begin{bmatrix} k \\ j \end{bmatrix}_q B_k^n(x;q) = \begin{bmatrix} n \\ j \end{bmatrix}_q x^j. \tag{1.15}$$

Theorem 1.2 (*cf.* [8], [7])**.** *If* $|q| < 1$*, and* $k = n$ *then*

$$\int_0^1 B_k^n(x;q) \, d_q x = \frac{1}{[n+1]_q}$$

and if $|q| < 1$*, and* $k = 0, \ldots, n-1$ *then*

$$\int_0^1 B_k^n(x;q) \, d_q x = \frac{q^{k+1}}{[n+1]_q}. \tag{1.16}$$

Theorem 1.3 (*cf.* [8])**.** *If* $|q| > 1$ *and* $k = 0, \ldots, n$*, then*

 ISBN: 978-84-617-8694-7

2 Main Results

In this section, by using q-calculus methods and q-Bernstein basis functions, we derive some combinatorial sums.

By applying q-integral to both side of the equation (1.15) from 0 to 1 and combining with (1.13) and (1.16), we arrive at the following theorem:

Theorem 2.1. *Let $k = 0, 1, \ldots, n-1$. Then, we have*

$$\sum_{k=j}^{n} \begin{bmatrix} k \\ j \end{bmatrix}_q q^{k+1} = \begin{bmatrix} n \\ j \end{bmatrix}_q \frac{[n+1]_q}{[j+1]_q}. \tag{2.1}$$

Remark 2.2. *If $q \to 1$, the equation (2.1) reduce to*

$$\sum_{k=j}^{n} \binom{k}{j} = \binom{n}{j} \frac{n+1}{j+1}$$

which is given by the author in [12, Theorem 5.5].

Since

$$[n+1]_q = [n+1]_q [n]_q!,$$

equation (2.1) reduces to the following identity:

Corollary 2.3. *Let $k = 0, 1, \ldots, n-1$. Then, we have*

$$\sum_{k=j}^{n} \begin{bmatrix} k \\ j \end{bmatrix}_q q^{k+1} = \begin{bmatrix} n+1 \\ j+1 \end{bmatrix}_q. \tag{2.2}$$

By applying q-integral to both side of the equation (1.15) from 0 to 1 and combining with (1.14) and (1.17), we arrive at the following theorem:

Theorem 2.4. *Let $k = 0, 1, \ldots, n-1$. Then, we have*

$$\sum_{k=j}^{n} \begin{bmatrix} k \\ j \end{bmatrix}_q q^{k} = q^j \begin{bmatrix} n \\ j \end{bmatrix}_q \frac{[n+1]_q}{[j+1]_q}. \tag{2.3}$$

Remark 2.5. *If $q \to 1$, the equation (2.3) reduce to the equation (2.2).*

Similarly, we have the following identity:

Corollary 2.6. *Let $k = 0, 1, \ldots, n-1$. Then, we have*

$$\sum_{k=j}^{n} \begin{bmatrix} k \\ j \end{bmatrix}_q q^{k} = q^j \begin{bmatrix} n+1 \\ j+1 \end{bmatrix}_q. \tag{2.4}$$

By applying q-integral to both side of the equations (1.10) and (1.11) from 0 to 1 respectively, and combining with (1.14) and (1.17), we arrive at the following lemmas:

 ISBN: 978-84-617-8694-7

Lemma 2.7.

$$\int_0^1 B_{n+1,q}(f)(x)\, d_{1/q}x = \sum_{k=0}^{n+1} \begin{bmatrix} n+1 \\ k \end{bmatrix}_q \Delta^k f_0 \frac{q^k}{[k+1]_q}. \tag{2.5}$$

Lemma 2.8.

$$\int_0^1 B_{n+1,q}(f)(x)\, d_{1/q}x = \sum_{i=0}^{n+1} f\left(\frac{[i]_q}{[n+1]_q}\right) \frac{q^k}{[n+2]_q}. \tag{2.6}$$

Combining (2.5) with (2.6)' we get the following theorem:

Theorem 2.9.

$$\sum_{k=0}^{n+1} \begin{bmatrix} n+1 \\ k \end{bmatrix}_q \Delta^k f_0 \frac{q^k}{[k+1]_q} = \sum_{i=0}^{n+1} f\left(\frac{[i]_q}{[n+1]_q}\right) \frac{q^k}{[n+2]_q}. \tag{2.7}$$

3 Remarks and Observations

By combining (1.2), (1.8) and (1.9), one may obtain not only some fundamental properties of the generating functions for the q-Bernstein basis functions and their functional equations, but also recurrence relations and derivative formulas for these functions. Moreover, one also may give some comments and observations on the q-Bernstein basis functions and the Bernstein basis functions. And also, one may simulate the results by their plots of these functions.

Abstract

n this short note, we study the article of Xin et al. [J. Nonlinear Sci. Appl., (9) 2016] and unexpectedly notice that the common fixed point result of this article do not produce any new result in literature. In fact the main results of this article coincide with some consequences of previous published results.

Key words: C^*-algebra, common fixed point
MSC 2000: 47H10, 54H25.

ISBN: 978-84-617-8694-7

1 Introduction

In 2014, Ma et al. [4] introduced the concept of C^*-algebra-valued metric space and presented some fixed point results for mappings satisfying contractive or expansive conditions in this space. Many researchers have already done their research in this structure but surprisingly Kadelburg and Radenović [1] and Alsulami et al. [5] observed that the all these results in this structure can be directly deduced as consequences of different fixed point results in standard metric and other related structures of metric counterpart. Recently, Xin et al. [7] presented common fixed point results on C^*-algebra-valued metric spaces. They established the following result.

Theorem 1.1 *Let $(X, \mathcal{A}, d)$ be a complete C^*-algebra-valued metric space. Suppose that two mappings $T, S : X \to X$ satisfy*

$$d(Tx, Sy) \preceq a^* d(x, y)a$$

for any $x, y \in X$ and $a \in \mathcal{A}$ with $||a|| < 1$. Then T and S have a unique common fixed point in X.

In this article we show that actually the mapping T is identical with S i.e. $Tx = Sx$ for all $x \in X$. Hence the Theorem 1.1 coincides with the result of Ma et al. [4]. Also, the authors of [7] proved the following theorem as a corollary.

Theorem 1.2 *Let $(X, \mathcal{A}, d)$ be a complete C^*-algebra-valued metric space. Suppose that the mapping $T : X \to X$ satisfies*

$$d(T^m x, T^n y) \preceq a^* d(x, y)a$$

for any $x, y \in X$; $a \in \mathcal{A}$ with $||a|| < 1$ and m, n are any positive integers. Then T has a unique fixed point in X.

In next section, we show that every point $x \in X$, $T^n x$ is a fixed point of T whenever $m > n$.

In 2007, Huang and Zhang [6] introduced the concept of cone metric spaces. Later on, Radenović and Kadelburg [2] showed that every cone metric space (X, d) with a normal solid cone and normal constant $K = 1$ is identical with standard metric space. Hence, the common fixed point results in cone metric spaces presented by Abbas and Jungck [3] also hold if we consider the underlying space as standard metric space. Here, we consider the common fixed point results of Abbas and Jungck [3] in the context of standard metric spaces.

Theorem 1.3 *Let (X, d) be a standard metric space. Suppose that the mappings $T, S : X \to X$ satisfy either of the following conditions:*

 ISBN: 978-84-617-8694-7

(C1) $d(Tx,Ty) \leq kd(Sx,Sy)$,

(C2) $d(Tx,Ty) \leq k[d(Tx,Sx)+d(Ty,Sy)]$,

(C3) $d(Tx,Ty) \leq k[d(Tx,Sy)+d(Ty,Sx)]$

for any $x,y \in X$ *and* $k \in [0,1)$ *for* $(C1)$ *contraction and* $k \in [0,\frac{1}{2})$ *for rest of the contractions. If* $R(T) \subset R(S)$ *and* $R(S)$ *is complete in* X*, then* S *and* T *have unique point of coincidence in* X*. Also, if* S *and* T *are weakly compatible, then there exists a unique common fixed point of* S *and* T *in* X*.*

2 Main result

In this section, we show that the results presented by Xin et al. [7] do not produce any new idea in literature.

Theorem 2.1 *Let* $(X,\mathcal{A},d)$ *be a* C^**-algebra-valued metric space. Suppose that two mappings* $T,S : X \to X$ *satisfy*

$$d(Tx,Sy) \preceq a^*d(x,y)a$$

for any $x,y \in X$ *and* $a \in \mathcal{A}$ *with* $||a|| < 1$*. Then* $Tx = Sx$ *for all* $x \in X$*.*

Proof. Let $x \in X$. Then from the hypothesis of the theorem we have

$$d(Tx,Sx) \preceq a^*d(x,x)a \quad \Rightarrow d(Tx,Sx) \preceq \theta.$$

Thus we have that for all $x \in X$, $Tx = Sx$. Hence, S and T are identical.

Remark 2.2 *From the above theorem we observe that Theorem 1.1 does not give anything new and it coincides with the fixed point result in* C^**-algebra-valued metric space [4, p.4, Theorem 2.1]. On the other hand Kadelburg and Radenović [1] and Alsulami et al. [5] independently proved that fixed point results in this space are the direct consequences of metric fixed point results. Hence this result contributes nothing new.*

Theorem 2.3 *Let* $(X,\mathcal{A},d)$ *be a complete* C^**-algebra-valued metric space. Suppose that the mapping* $T : X \to X$ *satisfies*

$$d(T^mx,T^ny) \preceq a^*d(x,y)a$$

for any $x,y \in X$*;* $a \in \mathcal{A}$ *with* $||a|| < 1$ *and* m,n *are any positive integers. Then every point* $x \in X$*,* T^nx *is a fixed point of* T *whenever* $m > n$*.*

 ISBN: 978-84-617-8694-7

Proof. As previous case, for all $x \in X$ and for $m > n$, we obtain

$$\begin{aligned} d(T^m x, T^n x) \preceq a^* d(x,x)a \quad &\Rightarrow \quad d(T^m x, T^n x) \preceq \theta \\ &\Rightarrow \quad T^m x = T^n x \\ &\Rightarrow \quad T^{m-n}(T^n x) = T^n x, \end{aligned}$$

which implies that $T^n x$ is fixed point of T for every $x \in X$ and for all $n \in \mathbb{N}$.

Next, we pick up the following result from [7].

Theorem 2.4 *Let $(X, \mathcal{A}, d)$ be a complete C^*-algebra-valued metric space. Suppose that two mappings $T, S : X \to X$ satisfy*

$$d(Tx, Ty) \preceq a^* d(Sx, Sy)a$$

for any $x, y \in X$ and $a \in \mathcal{A}$ with $||a|| < 1$. If $R(T) \subset R(S)$ and $R(S)$ is complete in X, then S and T have unique point of coincidence in X. Also, if S and T are weakly compatible, then there exists a unique common fixed point of S and T in X.

Now, we prove the following result.

Theorem 2.5 *Theorem 2.4 is equivalent with Theorem 1.3.*
Proof. In Theorem 2.4, if we consider $\mathcal{A} = \mathbb{R}$, absotule value as norm and $a^* = a$ for involution then we obtain

$$d(Tx, Ty) \leq a^2 d(Sx, Sy)$$

for all $x, y \in X$ and $a^2 \in [0, 1)$. Then clearly the contraction principle of the Theorem 2.4 coincides with the contraction $(C1)$ in Theorem 1.3.

On the other hand, we consider the hypotheses of Theorem 2.4. Then by choosing $\tilde{d}(x, y) = ||d(x, y)||$, obviously, one can get

$$\tilde{d}(Tx, Ty) = ||d(Tx, Ty)|| \leq ||a^* d(Sx, Sy)a|| \leq ||a||^2 \tilde{d}(x, y)$$

where $||a||^2 \in [0, 1)$. Hence by Theorem 1.3 with $(C1)$ contraction principle, S and T have unique coincidence point. Also, if the mappings are weakly compatible then they have unique common fixed point in X.

Remark 2.6 *In a similar fashion, one can see that the Theorem 2.9 and Theorem 2.10 in Xin et al. [7] are equivalent to Theorem 1.3 with $(C2)$ and $(C3)$ contraction principles respectively.*

Abstract

We derive stochastic versions of epidemiological models with severe and asymptomatic infection, which have previously been described as differential equation systems, and fit data output of these models with simpler SIR type models to obtain numerically effective infection rates from likelihoods. The results can be compared with the previously stated simpler analytical arguments for the relation between effective infection rate in the SIR models and more complex parameter combinations in the SHAR models via comparing stationary states. The tool box can be extended to be used to perform numerically Bayesian model comparison via the Bayes factor, as described in previous simpler epidemiological models, like the linear infection model or the Poisson model, in which all steps towards the Bayes factor could be performed analytically. The role of asymptomatic infection contributing to the force of infections is of special interest e.g. in the dengue fever epidemiology, as well for primary infections, which is often mild or asymptomatic, as well as for secondary infections, where the majority of hospitalizations occur but also not always leading to severe disease.

Key words: asymptomatic versus severe infection, stochastic processes, numerical likelihood functions, Bayes factor, dengue fever

ISBN: 978-84-617-8694-7

1 Introduction

In many diseases the infection is not always severe or even symptomatic. Hence the number of notified cases can differ from the number of infectious individuals. Then one of the key questions is in how far asymptomatic infected are infectious to susceptibles. We derive stochastic versions of epidemiological models with severe and asymptomatic infection, which have previously been described as differential equation systems [1]. Here we derive stochastic versions of such processes and fit data output of these models with simpler SIR type models to obtain numerically effective infection rates. The results can be compared with the previously stated simpler analytical arguments for the relation between effective infection rate in the SIR models and more complex parameter combinations in the SHAR models [1]. Namely, the relation between effective infection rate in the SIR system and the parameters of the SHAR model is confirmed by numerically evaluating the likelihoods of initial infection rate of the SHAR model and the effective infection rate of the SIR system, even outside stationarity of the respective processes, from which the analytical results were obtained in [1].

The tool box can be extended to be used to perform numerically Bayesian model comparison via the Bayes factor. We described this in previous simpler epidemiological models, in which all steps towards the Bayes factor could be performed analytically [2]. Similar approaches as we use here for the numerical calulation of likelihoods and Bayes factors have been used e.g. in [3, 4]. In our case study it turns out that the SHAR model, from which the toy data were generated, appears to be not much more likely than the effective SIR model in terms of Bayes factors. For alternative approaches of model selection, based on the Kolmogorov-Smirnov test, see e.g. [5]. However, such approaches are not as easily generalizable as the Bayes factor, where simply probabilities are given to models based on data.

The present study of such initial models is well applicable to the situation of dengue fever infections in which severity of disease is associated with antibody dependent enhancement (ADE) since a long time [6, 7]. And recently field studies tried to clarify the question if asymptomatically infected are equally infectious as severe cases with their high viral load [8]. These authors come to the conclusion that asymptomatically infected can infect as much mosquitoes as severely infected, and there is the expectation that due to their mobility, asymptomatically infected might even contribute more to the force of infection than severe cases. However, the best notification data of dengue infections from Thailand use only severe cases being hospitalized [9], which means that in relatively simple models which already can describe the empirical data well we would expect an "masked" effective infection rate as suitable rather than a "bare" infection rate, however this might be defined. Many present models of dengue fever have so complicated structures that any systematic analysis in terms of Bayes factors would most likely prefer the simpler models due to the limited number of empirical data. However, such effective models are the best tools for realistic predictions

 ISBN: 978-84-617-8694-7

of future disease levels [10], and even more in analysis of control measures like vaccination and its impact [11, 12, 13]. In the present study we concentrate on rather simplified models like the SHAR and SIR model without any serotype interactions, which would be needed to describe the empirical data more accurately [14, 15, 16]. Since such multi-strain models show not only oscillations into stationary states, and eventually stabilized by noise as we observe here in our simple models, but chaotic attractors, we will leave the study of such models with the present techniques for future research. For chaotic systems up to now mostly random walks toward the likelihood maximum are in technical reach, see [17] including further references. Hence future studies on such complex systems with mutli-strain interaction have to be performed.

2 The SHAR model

The SHAR model with severe infection or hospitalized cases H and mild or asymptomatic cases A in an otherwise SIR-type epidemiological model, see [18] for more information on the notations and standart analysis techniques, is given by

$$\begin{aligned} \frac{d}{dt}S &= \alpha R - \frac{\beta}{N}S(A+\phi H) \\ \frac{d}{dt}H &= \eta\frac{\beta}{N}S(A+\phi H) - \gamma H \\ \frac{d}{dt}A &= (1-\eta)\frac{\beta}{N}S(A+\phi H) - \gamma A \\ \frac{d}{dt}R &= \gamma(A+H) - \alpha R \end{aligned} \tag{1}$$

and $R = N - S - A - H$. Here η is the ratio of infection leading to severe disease cases and ϕ is the change of infectivity of severe cases versus the "natural" infectivity via asymptomatic cases.

The role of asymptomatic infection becomes more recognized recently, since many pathogens appear as only accidentally pathogenic, see e.g. [18, 19] initially for bacterial meningitis [20, 21, 22], with fluctuations similar to crossing a vaccination threshold [23]. Similarly, in dengue fever the virus is completely asymptomatic in its animal reservoir, monkeys, and only turns occasionally pathogenic in humans, mostly in secondary infections. The SHAR model is an oversimplified model for dengue fever in the sense that higher viral load due to antibody dependent enhancement, ADE [6, 7], or lower infectivity due to hospitalization gives a ϕ different from unity, and the majority of primary infections is asymptomatic or mild (sub-clinical) with ratio $(1-\eta)$, but here we do not consider primary versus secondary infection nor any further serotype interaction as done in [14, 16].

 ISBN: 978-84-617-8694-7

2.1 The stochastic SHAR model

We now want to generate "toy data" via a stochastic version of the SHAR model via the Gillespie algorithm, see [18] including further references, with transitions given by the following reaction scheme

$$\begin{array}{ccc} S+A & \xrightarrow{\eta\beta} & H+A \\ \text{„} & \xrightarrow{(1-\eta)\beta} & A+A \\ S+H & \xrightarrow{\phi\eta\beta} & H+H \\ \text{„} & \xrightarrow{\phi(1-\eta)\beta} & A+H \\ H & \xrightarrow{\gamma} & R \\ A & \xrightarrow{\gamma} & R \\ R & \xrightarrow{\alpha} & S \end{array} \tag{2}$$

giving the master equation for the dynamics of the probabilities

$$\begin{aligned} \frac{d}{dt}p(S,H,A,t) &= \eta\frac{\beta}{N}(S+1)A\; p(S+1,H-1,A,t) \\ &\quad +(1-\eta)\frac{\beta}{N}(S+1)(A-1)\; p(S+1,H,A-1,t) \\ &\quad +\eta\frac{b}{N}(S+1)\phi(H-1)\; p(S+1,H-1,A,t) \\ &\quad +(1-\eta)\frac{\beta}{N}(S+1)\phi H\; p(S+1,H,A-1,t) \\ &\quad +\gamma(A+1)\; p(S,H,A+1,t) \\ &\quad +\gamma(H+1)p(S,H+1,A,t) \\ &\quad +\alpha(N-(S-1)-H-A)\; p(S-1,H,A,t) \\ &\quad -\left(\frac{\beta}{N}S(A+\phi H)+\gamma(A+H)+\alpha(N-S-H-A)\right)\; p(S,H,A,t) \quad . \end{aligned} \tag{3}$$

The master equation can be written in a generic form using densities $x_1 := S/N$, $x_2 := H/N$ and $x_3 := A/N$ instead of the total numbers of individuals in the population classes S, H and A, hence state vector $\underline{x} := (x_1, x_2, x_3)^{tr}$, as

$$\frac{d}{dt}\; p(\underline{x},t) \;=\; \sum_{j=1}^{n}\Big(\; Nw_j(\underline{x}+\Delta\underline{x}_j)\cdot p(\underline{x}+\Delta\underline{x}_j,t) \;\; - Nw_j(\underline{x})\cdot p(\underline{x},t)\Big) \tag{4}$$

 ISBN: 978-84-617-8694-7

with $n = 5$ different transitions and small deviation from state $\underline{x}$ as $\Delta\underline{x}_j := \frac{1}{N} \cdot \underline{r}_j$. For the SHAR model we have explicitly the following transitions $w_j(\underline{x})$ and its vectors $\underline{r}_j$ given by

$$\begin{array}{lll} w_1(\underline{x}) = \eta\beta x_1(x_3 + \phi x_2) & , & \underline{r}_1 = (1,-1,0)^{tr} \\ w_2(\underline{x}) = (1-\eta)\beta x_1(x_3 + \phi x_2) & , & \underline{r}_2 = (1,0,-1)^{tr} \\ w_3(\underline{x}) = \gamma x_2 & , & \underline{r}_3 = (0,1,0)^{tr} \\ w_4(\underline{x}) = \gamma x_3 & , & \underline{r}_4 = (0,0,1)^{tr} \\ w_5(\underline{x}) = \alpha(1 - x_1 - x_2 - x_3) & , & \underline{r}_5 = (-1,0,0)^{tr} \quad . \end{array} \tag{5}$$

With these $w_j(\underline{x})$ and $\underline{r}_j$ specified we also can express the mean field ODE system and in Kramers-Moyal approximation of the master equation to a Fokker-Planck equation a stochastic differential equation system, as will be shown below. From the SHAR model given as master equation we can now simulate realizations of the stochastic process via the Gillespie algorithm, and in this way obtain a "toy data set"

$$\underline{D} := (H_1, H_2, ..., H_{n_d}) \tag{6}$$

of n_d data points of hospital cases H_ν at times t_ν. On this data set we can then test statistical methods to fit parameters of various models including model comparison in a Bayesian framework. We will now try to describe the output of the SHAR model $\underline{D}$ via an effective simpler model, the SIR model with new infection rate $\tilde{\beta}$.

3 The effective SIR model

An effective SIR model tries to explain the observed number of infected via a simple infection class I without any further distinction into more complex classes like asymtomatically infected, severe cases or any other possible mechanisms like primary or secondary infection etc. The SIR model is given by

$$\begin{aligned} \frac{d}{dt}S &= \alpha R - \frac{\tilde{\beta}}{N} SI \\ \frac{d}{dt}I &= \frac{\tilde{\beta}}{N} SI - \gamma I \\ \frac{d}{dt}R &= \gamma I - \alpha R \end{aligned} \tag{7}$$

with an initially unknown infection rate $\tilde{\beta}$ and to be determined either from data as we will do below, or as was done in [1], by assuming that the effective SIR system has the same stationary state value I^* as a more complex model, here the SHAR model with observed severe infected H^*.

 ISBN: 978-84-617-8694-7

3.1 Effective infection rate

In [1] we obtained for the effective infection rate $\tilde{\beta}$ as a function of the parameters of the more complex model, the SHAR model, the expression

$$\tilde{\beta} = \frac{\gamma}{1 - \eta\left(1 - \frac{1}{1+(\phi-1)\eta} \cdot \frac{\gamma}{\beta}\right)} \tag{8}$$

from assuming the condition that the stationary state I^* of the effective SIR model is the same as the stationary state value of the observed severe cases H^* in the SHAR model, hence $I^*(\tilde{\beta}) = H^*(\beta, \eta, \phi)$. It turned out that also outside stationarity the deterministic simulations of the SHAR model and the effective SIR model with the above determined effective infection rate $\tilde{\beta}$ agree quite well, when using otherwise the same parameters and initial conditions, as far as the SIR system has corresponding parameters in the SHAR model, see Fig. 1.

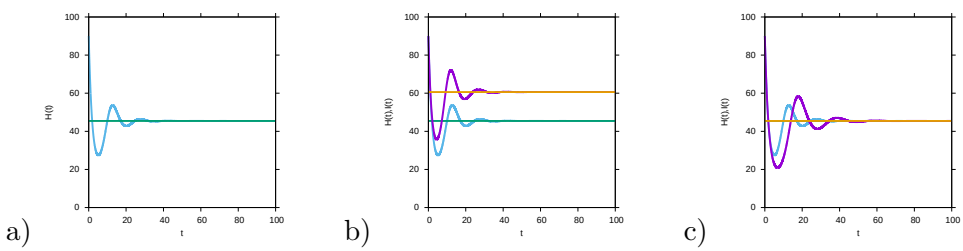

Figure 1: *Comparison between deterministic SHAR model and SIR model, also outside the stationary state. a) The trajectory of the severe diseased cases $H(t)$ of the SHAR model oscillating into the stationary state H^* after a transient. b) In comparison also the number of infected $I(t)$ from the SIR model with still $\tilde{\beta} = \beta$, in comparison to $H(t)$ from the SHAR model. c) Now we use the effective infection rate in the effective SIR model, hence $\tilde{\beta} = \tilde{\beta}(\alpha, \beta, \gamma, \eta)$ from $I^* = H^*$, Eq. (8).*

Parameters for the initial study of the deterministic matching are given as follows: For the SHAR model we use $N = 1000$, $\gamma = 1$, $\beta = 3 \cdot \gamma$, $\alpha = 0.1$, $\eta = 3/4$, and for the moment $\phi = 1$. Initial conditions are $S_0 = 200$, $A_0 = 30$, $H_0 = \frac{\eta}{1-\eta} A_0$, a relation which holds in stationarity $H^* = \frac{\eta}{1-\eta} A^*$, and $R_0 = N - S_0 - A_0 - H_0$. For the SIR system we use the same parameters if not otherwise stated, hence initially $\tilde{\beta} = \beta$, see Fig. 1 b), and as initial conditions $S_{0,SIR} = (\beta/\tilde{\beta}) S_{0,SHAR}$, $I_0 = H_0$ and $R_0 = N - S_0 - I_0$. In Fig. 1 c) we use the analytically calculated effective infection rate Eq. (8), which turns with the present $\eta = 3/4$ etc. out to be $\tilde{\beta} = 2 \cdot \gamma$. In Fig. 2 b) we also change the intial condition in the SHAR model to $A_0 = 100$ to observe the effect of initial conditions far away from the equilibrium, and still $I(t)$ is quite well comparable with $H(t)$ outside the condition $I^* = H^*$.

 ISBN: 978-84-617-8694-7

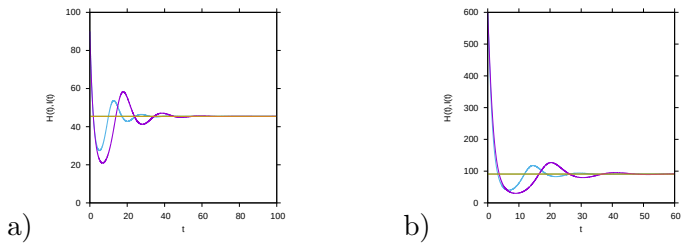

Figure 2: *The comparison of deterministic SHAR and SIR models for varying initial conditions. a)* $A_0 = 30$ *and b)* $A_0 = 100$ *and* $N = 2000$*. Even transients far out of equilibrium of the SHAR model are matched quite well via the transient of the effective SIR model, though the effective parameters are determined only by the stationary state condition* $I^* = H^*$*.*

Next we look at the master equation formulation of the SHAR model to simulate toy data. For a comparison of the stochastic version as compared to the deterministic see Fig. 3. The stochastic fluctuations of the SHAR model itself go well beyond the differences between the SHAR model and the effective SIR in their deterministic versions. In the present study we want to determin the effective infection rate $\tilde{\beta}$ by comparing stochastic simulations of the effective SIR model with the data $\underline{D}$ obtained from a stochastic simulation of the SHAR model. For this we vary values of $\tilde{\beta}$ and count the number of simulations being close to the data, and the $\tilde{\beta}$ value with maximal number of simulations close to the data is the best estimator of $\tilde{\beta}$ for this data set. Therefore, we now need the stochastic version of the effective SIR model, and best a version which is quick in simulation time, since we need many simulations with varying $\tilde{\beta}$ values.

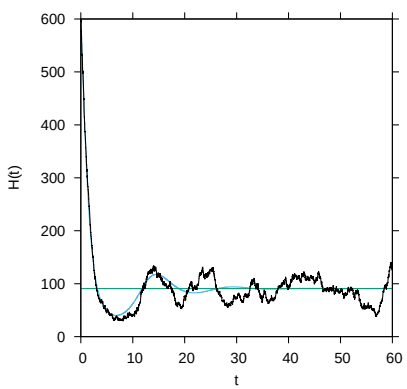

Figure 3: *Stochastic realization via the Gillespie algorithm from the master equation of the SHAR model in comparison with the deterministic mean field system.*

 ISBN: 978-84-617-8694-7

3.2 Stochastic versions of the effective SIR model

The master equation for the effective SIR model is given by the reaction scheme

$$\begin{array}{rcl} S+I & \xrightarrow{\tilde{\beta}} & I+I \\ I & \xrightarrow{\gamma} & R \\ R & \xrightarrow{\alpha} & S \end{array} \tag{9}$$

and explicitly for the dynamics of the probabilities

$$\begin{aligned} \frac{d}{dt}p(S,I,t) &= \frac{\tilde{\beta}}{N}(S+1)(I-1)\ p(S+1,I-1,t) \\ &\quad +\gamma(I+1)p(S,I+1,t) \\ &\quad +\alpha(N-(S-1)-I)\ p(S-1,I,t) \\ &\quad -\left(\frac{\tilde{\beta}}{N}SI+\gamma I+\alpha(N-S-I)\right)\ p(S,I,t) \quad . \end{aligned} \tag{10}$$

For the master equation in densities $x_1 := S/N$ and $x_2 := I/N$ we have now transitions $w_j(\underline{x})$ and its vectors $\underline{r}_j$ given by

$$\begin{array}{lll} w_1(\underline{x}) = \tilde{\beta}x_1x_2 & , & \underline{r}_1 = (1,-1)^{tr} \\ w_2(\underline{x}) = \gamma x_2 & , & \underline{r}_2 = (0,1)^{tr} \\ w_3(\underline{x}) = \alpha(1-x_1-x_2) & , & \underline{r}_3 = (-1,0)^{tr} \quad . \end{array} \tag{11}$$

We could use now simulations of the master equation directly to measure the effective infection rate $\tilde{\beta}$, but for large population sizes N the simulations become very slow. So we will use the Kramers-Moyal expansion to obtain a Fokker-Planck equation as approximation of the master equation, for which the corresponding stochastic differential equation system can be simulated much faster.

3.3 Fokker-Planck approximation of the effective SIR model

From the master equation in densities, Eq. (4), now for the SIR system, we use Taylor's expansion

$$w_j(\underline{x}+\Delta\underline{x}_j)\cdot p(\underline{x}+\Delta\underline{x}_j,t) = \sum_{\nu=0}^{\infty}\frac{1}{\nu!}\left(\Delta\underline{x}_j\cdot\nabla_{\underline{x}}\right)^{\nu} w_j(\underline{x})\ p(\underline{x},t) \tag{12}$$

 ISBN: 978-84-617-8694-7

giving to second order in $1/N$ a Fokker-Planck equation

$$\begin{aligned} \frac{\partial}{\partial t}\, p(\underline{x},t) &= -\nabla_{\underline{x}} \left(\sum_{j=1}^{n} (-\underline{r}_j \cdot w_j(\underline{x}))\, p(\underline{x},t) \right) \\ &\quad + \frac{\sigma^2}{2} \sum_{j=1}^{n} (\underline{r}_j \cdot \nabla_{\underline{x}})^2 w_j(\underline{x})\, p(\underline{x},t) \end{aligned} \tag{13}$$

with

$$\nabla_{\underline{x}} = \begin{pmatrix} \frac{\partial}{\partial x_1} \\ \frac{\partial}{\partial x_2} \end{pmatrix} = \partial_{\underline{x}} \tag{14}$$

or in different notation

$$\frac{\partial}{\partial t}\, p(\underline{x},t) = -\partial_{\underline{x}} \left(\underline{f}(\underline{x})\, p(\underline{x},t) \right) + \frac{\sigma^2}{2} \overrightarrow{\partial}_{\underline{x}} \left(G^2(\underline{x})\, p(\underline{x},t) \right) \overleftarrow{\partial}_{\underline{x}} \tag{15}$$

using simply a quadratic form $\overrightarrow{\partial}_{\underline{x}} \left(G^2(\underline{x})\, p(\underline{x},t) \right) \overleftarrow{\partial}_{\underline{x}}$ here with

$$\overrightarrow{\partial}_{\underline{x}} \left(G^2\, p \right) \overleftarrow{\partial}_{\underline{x}} = \left(\frac{\partial}{\partial x_1}, \frac{\partial}{\partial x_2} \right) \cdot \begin{pmatrix} g_{11} & g_{12} \\ g_{21} & g_{22} \end{pmatrix}^2 p(\underline{x},t) \cdot \begin{pmatrix} \overleftarrow{\frac{\partial}{\partial x_1}} \\ \\ \overleftarrow{\frac{\partial}{\partial x_2}} \end{pmatrix} \tag{16}$$

and

$$\begin{aligned} \underline{f}(\underline{x}) &= \sum_{j=1}^{n} \underline{f}_j(\underline{x}) = \sum_{j=1}^{n} (-\underline{r}_j \cdot w_j(\underline{x})) \\ G^2(\underline{x}) &= \sum_{j=1}^{n} G_j^2(\underline{x}) = \sum_{j=1}^{n} \underline{r}_j \cdot \underline{r}_j^{tr}\, w_j(\underline{x}) \quad . \end{aligned} \tag{17}$$

The Fokker-Planck equation gives a stochastic differential equation system with $\sigma = 1/\sqrt{N}$ and in the XYZ case the two dimensional Gaussian normal noise vector $\underline{\varepsilon}(t) = (\varepsilon_{x_1}(t), \varepsilon_{x_2}(t))^{tr}$ as

$$\frac{d}{dt}\underline{x} = \underline{f}(\underline{x}) + \sigma G(\underline{x}) \cdot \underline{\varepsilon}(t) \tag{18}$$

and using matrix square root from eigenvalue-eigenvector decomposition $G^2(\underline{x}) = T \Lambda T^{-1}$ as $G(\underline{x}) = T \sqrt{\Lambda} T^{tr}$ to be numerically implemented easily, and much faster than the Gillespie algorithm for the master equation.

 ISBN: 978-84-617-8694-7

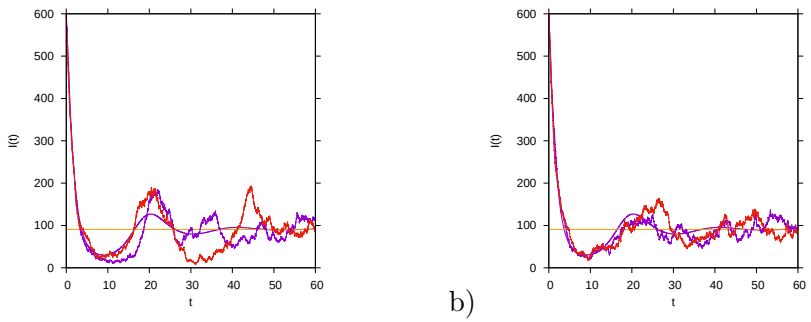

Figure 4: *Stochastic realizations via the Gillespie algorithm from the master equation (pink) and from the stochastic differential equation system (red), of the SIR model in comparison with the deterministic mean field system. Shown are two different stochastic realizations, but otherwise same parameters and initial conditions.*

Now we can vary $\tilde{\beta}$ and compare in an η-ball method [24, 10] the simulations of the SIR model with the data vector $\underline{D}$, which gives the likelihood $p(\underline{D}|\tilde{\beta})$. The η as a radius of a vicinity around the data vector $\underline{D}$ should not be confused with one of the parameters in the SHAR model, which is also named η, a confusion easily avoided by the very different contexts in which they appear. In case of doubt, we will call η_{SHAR} the model parameter of the SHAR model, and η_1 the η-ball radius around the data, used to evaluate simulations from model M_1, and η_2 from model M_2.

4 Data and analysis, results and conclusions

From the SHAR model we now generate data sets, like given in Fig. 5, hoping that the data already contain so much information about the system to find back parameters with not too large variance. Especially, we take a transient behaviour and a long period in stationarity covered by the time interval of the data. The data are taken by the slow Gillespie algorithm.

Then we compare simulations of the SHAR model, see Fig. 6 a), with the data, where now the simulations are performed with the much faster stochastic differential equations obtained by the Fokker-Planck approximation of the master equation with its slow Gillespie algorithm for simulations. We finde accurately the best estimate to be where expected, at $\beta_1 = 3 \cdot \gamma$, and values like $\beta_1 = 2 \cdot \gamma$ or $\beta_1 = 4 \cdot \gamma$ have already quite lower likelihood, this in spite of using different algorithms for data generation and model fitting.

The next result is, when fitting the effective SIR model to the data generated from the SHAR model, again using the stochastic differential equation approach, we obtain a best estimate from the maximum of the likelihood for the effective infection rate $\beta_2 = \tilde{\beta} = 2 \cdot \gamma$, in good agreement with out analytical result, Eq. (8). This is a non-trivial result, since

 ISBN: 978-84-617-8694-7

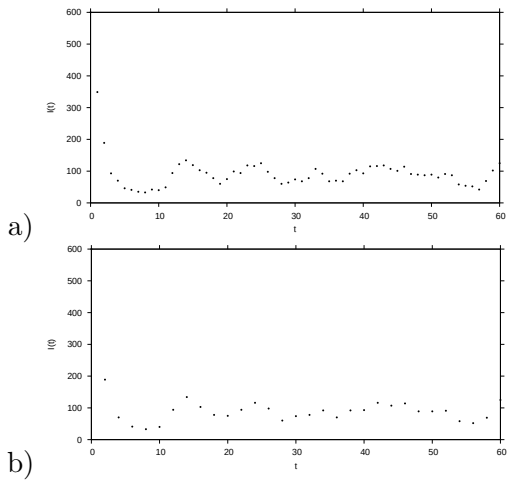

Figure 5: *Data taken from the SHAR model with different sampling times, reflecting different knowledge about the fluctuations in the system. a) Sampling time is one unit, here in units of recovery times since we set $\gamma = 1$, in b) sampling time are two units.*

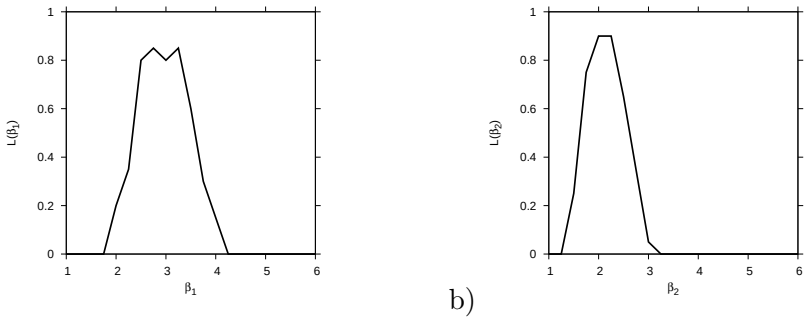
we obtained the analytic expression via comparing stationary states $I^* = H^*$ only, but now obtain the same relation from simulated data outside stationarity with a long and oscillating transient and continued stochastically stabilized oscillations in stationarity. Also remarkable is that for $\beta_2 = \tilde{\beta}$ the value of $3 \cdot \gamma$, which is the one used in the SHAR model, can be statistically excluded.

Finally, we investigate the Bayes factor $k = p(M_1|\underline{D})/p(M_2|\underline{D})$ for a data set $\underline{D}$ generated from M_1, the SHAR model. Fo more details on the Bayes factor and analytic results in simple cases see [2]. A Bayes factor of $k = 1$ would indicate equal probability of both models M_1, the SHAR model, and M_2, the effective SIR model, whereas $k >> 1$ would give much higher probability of model M_1 over model M_2, that the data could lead us to reject model M_2 statistically. In our case, considering the Bayes factor as

$$k = \int\int p(M_1, \beta_1, \eta_{SHAR}|\underline{D})\, d\beta_1 d\eta_{SHAR} \Big/ \int p(M_2, \beta_2|\underline{D})\, d\beta_2 \tag{19}$$

due to the fact that we have to estimate in the SHAR model M_1 not only β_1 but also η_{SHAR} while in the SIR model M_2 we only need β_2 to estimate (neglecting for the moment all other possible insecurities) first results, still in low numerical resolution, give a Bayes factor of $k = 127/81 = 1.57$ for 360 runs of each of the models and distance to data $\eta = 450$, hence the two models have about equal probability to describe the toy data set Fig. 5 a). But future studies have to be performed to investigate this point in more detail, including the question of ensembles of realizations and their Bayes factors, hence the fluctuations of the Bayes factor, as could be performed in the simpler analytically treatable case study [2].



a) b)

Figure 6: *Likelihood measurement for a) model M_1 and b) model M_2. For model M_1 the best estimate is around $\beta_1 = 3$ as to be expected, since we set in generating the toy data set $\beta = 3\gamma$ and $\gamma = 1$. For model M_2 we obtain a best estimate around $\beta_2 = 2$, which agrees well with the analytically obtained effective $\tilde{\beta} = 2\gamma$, when using $\eta = 3/4$ in generating the toy data set.*

Further applications could be in ecology on Rosenzweig-MacArthur type models [25], and there on the Hudson Bay company data for hares and lynx furs, due to expected limit cycles rather than chaotic attractors as in dengue fever cases and its data from e.g. Thailand.

New numerical methods for PDE models related to pricing and expected lifetime of an extraction project

María Suárez-Taboada[1] **and Carlos Vázquez**[1]

Abstract

Mining companies face several uncertainties when they develop a mining project. There are many factors which provide randomness, such as the risk of political instability and the market fluctuations. These uncertainties will be reflected in the stock price of the commodity to be obtained, for example. In fact, variations of the price can be translated into the mine close down because it is no more profitable or just the opposite, the mining project can turn into a very profitable business. Other uncertain factors, such as the size of the resource inside the mine that can be extracted or the ore-grade of the mineral, also influence the value of the mining project and the probability of completing the extraction project.

In order to pose suitable mathematical models to obtain the value of the mining project, the probability of completing the extraction project and the expected life time, in [4] a methodology starting from Feynman-Kac theorem is followed. This methodology relates a expression of the problem solution in terms of expectations and the equivalent PDE formulation. Also the stochastic dynamics of the driving stochastic factors have to be chosen. For the commodity price we assume a geometric Brownian motion, while for the remaining resource we consider a constant extraction rate. In this way, the value of the mine with the option to close down is the solution of a complementarity problem associated to a PDE. When the ore-grade is assumed to be constant, the spatial variables of the PDE (which correspond to the considered stochastic factors) are the commodity price and the resource size. Therefore, the pricing problem involves a free boundary that represents the optimal abandonment boundary, which is part of the solution of the PDE problem. Moreover, the probability of project completion and the expected lifetime are the respective solutions of additional final-boundary value problems associated to the same differential operator that governs the mine value, although with different final and boundary conditions. We note that the resulting differential operator is highly

 ISBN: 978-84-617-8694-7

degenerated, as only the second order derivative with respect to the commodity price is not zero. In [4], the authors propose a first order characteristics method for time discretization combined with finite differences in space. For the complementarity problem, the propose a projected relaxation method. Also we note that some of the boundary conditions are not clear and properly justified.

In the present work, we propose a more rigorous statement of the appropriate boundary conditions. First, we follow the classical theory in [6] to determine the boundaries where boundary conditions are required. Secondly, in order to pose appropriate Dirichlet boundary conditions on some of these boundaries we apply some ideas already used in [2] for companies valuation models.

Next, taking into account the convection-dominating terms of the PDEs governing the mathematical models, we propose a higher order characteristics Crank-Nicholson method to discretize the time derivative jointly with the first order spatial derivative (i.e. the material derivative). For the spatial discretization related to the price and the remaining resource variables, we propose the use of piecewise quadratic Lagrange finite elements, so that the resulting fully discretization method falls into the framework of the so called Lagrange-Galerkin methods [1]. Additionally, in order to deal with the nonlinearity associated to the complementarity problem governing the mine pricing, the augmented Lagrangian active set method proposed from [5] is used. This set of numerical technique has been already successfully used in other problems related to pricing of pension plans and financial derivatives, such as in [3, 7, 8].

Finally, some numerical results will be shown in order to illustrate the performance of the proposed boundary conditions and numerical methods. More precisely, first an academic test with analytical solution illustrates the performance of the method. Secondly, a real mine example allows to obtain the expected behaviour for the mine value, the probability of completing the problem and the expected lifetime.

Key words: resources valuation problems, investment under uncertainty, complementarity problems, characteristics methods, finite elements, augmented Lagrangian active set methods

Abstract

The NACA 2412 profile was numerically studied via employing 2D-DNS and implementing Active Flow Control (AFC), the Reynolds number considered was 6757, being the angle of attack of 8°. Initially, the basic flow without implementing AFC was considered, the point in which the boundary layer separates as well as the y+ value along the profile length were evaluated. A single groove location, just before the separation point, was considered, periodic forcing was employed to both modify the location of the separation point and change the separation area where vortices are present. This was undertaken resulting in a reduction of the drag coefficient while increasing the lift. Via studying a set of frequencies and amplitudes linked with the AFC periodic actuation, it was obtained the optimum set of parameters to minimize the drag while maximizing the lift.

Key words: Active Flow Control, AFC, Periodic forcing, NACA 2412, Lift and Drag coefficients, DNS.

1 Introduction

Active Flow Control (AFC) is quite a recent technology used to modify fluid performance around bluff bodies. The essential idea behind AFC is to interact with the boundary layer in order to promote or delay flow separation, via doing so the downstream vortex

shedding amplitude and frequency can be modified and therefore lift and drag coefficients can be consequently affected. There are several ways to implement AFC in a bluff body, via using plasma actuators, via employing steady suction, steady blowing, periodic forcing and implementing zero net mass flow actuaors (ZNMFA) or using fluidic actuators (FA). Plasma actuation appears at the moment to have some difficulties in sufficiently interacting with the incoming flow [1, 2], then it is simply ionizing the lower parts of the boundary layer and therefore produces a narrow influence on the overal flow performance. Steady suction/blowing, are clearly giving the required energy to the boundary layer to generate a drastic modification of it, these two technologies can be clearly implemented in the vast majority of bluff bodies, obtaining drastic effects on vortex shedding, such effect deeply depends on the parameter defined as velocity ratio [3, 4, 5]. Probably, the only drawback of steady blowing/suction is the energy required to perform the required boundary layer delay, quite often relatively high velocity ratios are required and therefore the energy required for the AFC implementation is higher than the saved one when considering its beneficial effects. The technology which appears to be more efficient in overcoming such drawback is the use of periodic forcing. Periodic forcing interacts directly with the natural flow instabilities, such as the Kelvin-Helmholtz instability, shear layer flapping and ring-shaped wake structures [6]. Thus, employing a relatively small amount of energy, can dramatically affect the boundary layer. Nevertheless, in order to be able to interact efficiently with the natural shear layer instabilities, it is important to locate the groove, in which fluid is sucked in or blown out, precisely. Compared with the location of the groove whenever steady sucking is employed, which is used to modify the boundary layer separation point being located whether upstream or downstream and even at some distance of it [7], the use of periodic forcing as well as steady blowing, require a groove location near the separation point. To obtain optimum efficiency, the groove needs to be located just upstream of the boundary layer separation point whenever no AFC is employed. These main guide lines were followed in the present research. In what follows the numerical procedure followed for the numerical simulation will be outlined.

2 Numerical Model and boundary conditions

In any numerical simulation, the first step to be accomplished is to check the validity of the mesh employed. To do so, performing a grid independence test is always a good procedure, comparing the results obtained with experimental ones or previous researchers simulations, falls as well into the standard procedure, for the present case, the simulation will be validated via checking the y+ parameter. Whenever the maximum value of this parameter is smaller than one, it can be concluded that there are enough cells inside the laminar sub boundary layer, and therefore, the shear stresses nearby the walls are meant to be properly simulated. Three different meshes were evaluated in the present simulation, when a mesh

 ISBN: 978-84-617-8694-7

with 93686 cells was employed, the maximum y+ was 1, whenever the mesh was refined to 107166 cells the value of maximum y+ decreased to 0.666, and when using 120646 cells, the maximum y+ value decreased to 0.333. Although not presented in this paper, the dynamic lift coefficient was plotted for the three meshes employed and it was observed, that the results obtained when using the two most refined meshes were much closer than the dynamic result obtained when using the coarse mesh. Notice that via performing the previous comparison, in reality the authors make sure that the Strouhal number obtained from the simulation is also properly determined. As a conclusion of this preliminary study it was decided to use the mesh with 107166 cells to perform the rest of the simulations.

Regarding the boundary conditions used in the simulations, table 1 summarizes them. The fluid used for the simulation was air at standard conditions, its density was of $\rho = 1.225 kg/m^3$, being its absolute viscosity of $\mu = 1.48 * 10^{-5} m^2/s$, the chord of the profile was 1 m, the angle of attack and Reynolds number were kept constant, its values were respectively of $\alpha = 8^\circ$ and Re = 6757, fluid was considered as incompressible.

Table 1: Boundary conditions applied for the URANS simulation model. No-slip condition applied on the wing surface and constant velocity condition on the inlet boundary. Front and back planes are empty due to two-dimensional setup.

Boundaries	Parameter	Boundary conditions	Value
Inlet	Velocity	Dirichlet	$U_\infty = 0.1 m/s$
	Pressure	Neumann	$\frac{\partial p}{\partial n} = 0$
Outlet	Velocity	Neumann	$\frac{\partial u}{\partial n} = 0$
	Pressure	Dirichlet	p=0 Pa
Profile surface	Velocity	Dirichlet	u=0
	Pressure	Neumann	$\frac{\partial p}{\partial n} = 0$
Front and Back	Velocity	–	–
	Pressure	–	–

In what follows, initially the basic flow without implementing AFC will be considered, the next step will be to evaluate the wing profile performance whenever AFC is considered.

3 Results

3.1 Baseline case

In order to obtain the location where the boundary layer separates from the body, the wall shear stress for the baseline flow was determined and presented in figure 1. The separation point is defined as the point where the wall shear stress becomes zero, from figure 1 it can be observed that the laminar bubble separation is occurring at around 0.15 % chord. But figure 1 presents another two points where shear stresses suddenly drop, these points are located at about 60% and 81% of the chord. During the simulation it was noticed an small fluctuation of these minimum stress locations, the fluctuation was due to the boundary layer motion triggered by the flapping mechanism and vortex shedding. In reality, after the first separation point an elongated vortex, which turns at clockwise direction, appears, this first elongated vortex is called the laminar separation bubble, the location at which this initial vortex ends, and a second much smaller counterclockwise vortex begins, is where the shear stresses reach the second minimum. As presented in figure 2, this second vortex triggers a third one which begins at the third minimum stress point and ends at the end on the chord. This third vortex is also an elongated one and turns clockwise. It must be clarified that the shape, location and even the number of vortices appearing onto the wing profile, keep changing versus time which indicates the existence of vortex shedding. Vortex shedding is mostly linked with the appearance and separation of the second and third vortices, the laminar separation bubble, although fluctuates, is not being shed downstream.

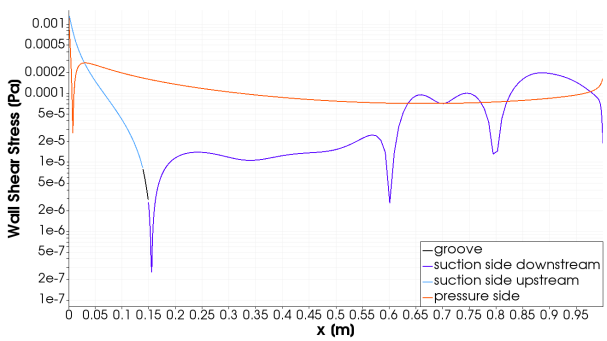

Figure 1: Wall shear stress vs. chord length of baseline case. The different colors show pressure and suction side of the wing as well as the location where flow control will be applied. Global minimum at 15 % of the chord represents flow separation point.

Among the information to be extracted from the baseline case, the vortex shedding frequency is particularly relevant, to obtain such frequency the fast fourier transform was applied to the temporal lift and drag coefficents, the result is presented in figure 3. It is

 ISBN: 978-84-617-8694-7

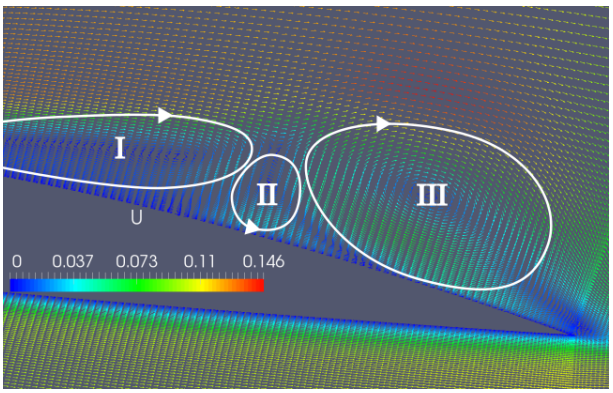

Figure 2: Main vortices appearing onto the wing surface shown in a velocity vector plot. Direction of rotation is shown by white arrows.

noticed that regardless of the coefficient chosen, the main frequency, which is the vortex shedding frequency, remains constant at 0.11 Hz. Accordng to previous studies [8, 9], among others, the frequency to be used whem employing periodic forcing to effectively interact with the unsteady shear layer, shall be around the natural vortex shedding frequency. A second parameter to be defined is the groove location, also based on previous studies [8, 9], it was found that whenever periodic forcing is employed, the most appropriate location for the groove is slightly upstream of the separation point, for the present simulation, the groove was located 1% of the chord (1 cm) upstream of the separation point. The groove width was as well 1% of the chord and the flow was injected perpendicular to the solid boundary.

3.2 Periodic forcing, frequency modification

In this section the effect of modifying the periodic forcing frequency will be explored. Five different non-dimensional frequencies were evaluated, F^+ 0.1; 0.5; 1; 5 and 10, $F^+ = 1$ characterizes the natural vortex shedding frequency obtained from the baseline case. The momentum coefficient was maintained constant and equal to $C_\mu = 1 * 10^{-3}$ for all these cases. The angle of attack $\alpha = 8^\circ$ was maintained constant as well during the entire study. In order to properly quantify the wing profile performance, temporal averaged lift and drag coefficients were recorded for each case and compared with the homologous obtained in the baseline case. A parameter defined as variation of performance, which compares the lift and drag coefficients increments versus the lift and drag coefficients obtained in the baseline case, see equation 1, was also employed to accurately determine the Active Flow Control advantages.

 ISBN: 978-84-617-8694-7

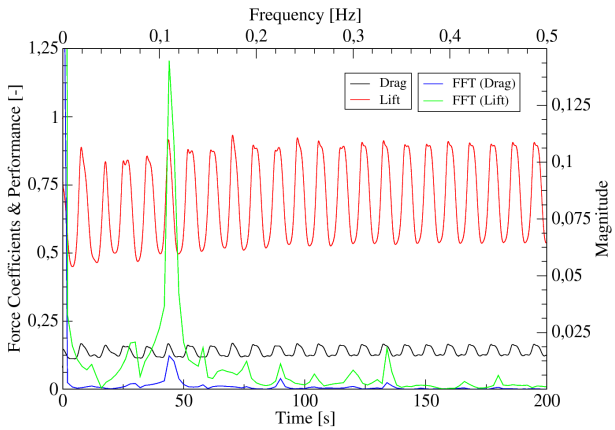

Figure 3: Fast Fourier Transformation (FFT) of lift coefficient C_L and drag coefficient C_D temporal signals. Main frequency at 0.11 Hz indicated by a significant peak of the green and blue curve.

$$\Psi = \frac{\Delta \frac{C_L}{C_D}}{\frac{C_{L_0}}{C_{D_0}}} \tag{1}$$

C_{L_0} and C_{D_0} represent the temporal averaged lift and drag coefficients from the baseline case.

Table 2 presents the lift and drag coefficients variation versus the respective baseline case values, the variation of the performance parameter, defined in equation 1 is also introduced. From this table it can clearly be seen that whenever the periodic forcing frequency is the same as the natural vortex shedding one, the wing performance is optimal, having the maximum lift and minimum drag, these results clearly agree with many of the former researchers undertaken, see for example [9, 10]. It is also interesting to observe, that regardless of the frequency used, a drag decrease is generated, although such decrease is particularly relevant at periodic forcing frequencies equal to the vortex shedding one or even half of it.

3.3 Periodic forcing, amplitude modification

Once obtained the most appropriate frequency to be employed, the next step was to evaluate the effect of the periodic forcing amplitude. For these new runs, the forcing frequency was maintained constant and equal to the vortex shedding one, five different forcing amplitudes were considered, which once non-dimensionalized in the form of the momentum coefficient, gave the following values $C_\mu = 1 * 10^{-4}; 5 * 10^{-4}; 1 * 10^{-3}; 5 * 10^{-3}; 1 * 10^{-2}$. The results

 ISBN: 978-84-617-8694-7

Table 2: Variation of wing parameters when modifying periodic forcing frequency resp. non-dimensional frequency. Relative change in performance, lift and drag compared to the values of baseline simulation.

$C_\mu = 1 * 10^{-3}$	Ψ	$\frac{\Delta C_L}{C_{L_0}}$	$\frac{\Delta C_D}{C_{D_0}}$
$F^+ = 0.1$	16.8%	8.3%	-2.4%
$F^+ = 0.5$	57.4%	12.2%	-26.2%
$F^+ = 1$	80.3%	12.8%	-35.2%
$F^+ = 5$	-2.5%	-9.8%	-5.8%
$F^+ = 10$	-0.8%	-1.9%	-0.6%

obtained from this second set of simulations are presented in table 3, where the same comparison paramenters used in table 2 were evaluated. When looking at table 3, it is very interesting to realize that all momentum coefficients used, generate a very high decrease on the drag coefficient, the maximum increase in lift it is obtained when using the minimum momentum coefficient, it is also interesting to notice that once a certain forcing amplitude was overcome, the lift coefficient drops to negative values and keeps decreasing as the forcing amplitude increases, this particular effect is very likely to be caused due to boundary layer tripping, the periodic forcing amplitude is higher than the boundary layer thickness at the injection point, therefore the energy associated to the pulsating flow is released outside the boundary layer, promoting stall.

Table 3: Variation of wing parameters when modifying periodic forcing velocity amplitude resp. momentum coefficient. Relative change in performance, lift and drag compared to the values of baseline simulation.

$F^+ = 1.0$	Ψ	$\frac{\Delta C_L}{C_{L_0}}$	$\frac{\Delta C_D}{C_{D_0}}$
$C_\mu = 1 * 10^{-4}$	66.9%	24.4%	-22.9%
$C_\mu = 5 * 10^{-4}$	73%	12%	-33%
$C_\mu = 1 * 10^{-3}$	80.3%	12.8%	-35.2%
$C_\mu = 5 * 10^{-3}$	61.8%	-2.5%	-37.5%
$C_\mu = 1 * 10^{-2}$	50.8%	-11.9%	-39.9%

 ISBN: 978-84-617-8694-7

3.4 Combining frequency and amplitude

In the present subsection, the combination of all results obtained from the previous cases will be introduced. In tables 4, 5 and 6, the values of the wing performance parameter Ψ, the lift gain $\frac{\Delta C_L}{C_{L_0}}$ and the drag gain $\frac{\Delta C_D}{C_{D_0}}$, will be respectively presented as a function of all the non dimensional frequencies and momentum coefficients evaluated. From these tables it is observed that the optimum wing performance increase $\Psi = 80.3\%$ it is obtained for the following set of conditions $F^+ = 1$ and $C_\mu = 1 * 10^{-3}$, lift and drag increase are respectively of 12.8% and -35.2%. Observing table 6, it is realized that the conditions required to obtain minimum drag are $F^+ = 1$ and $C_\mu = 1 * 10^{-2}$, if on the other hand, lift is to be maximized, according to table 5, the optimum set of parameters are $F^+ = 1$ and $C_\mu = 1 * 10^{-4}$. The conclusion is that employing a frequency matching the natural vortex shedding one, deeply affects the downstream flow performance, the variation of the forcing amplitude will generate weather a maximum lift, for small amplitudes, or a minimum drag, for big amplitudes, or even an optimum wing performance parameter, obtained for medium amplitudes. Whenever the periodic forcing frequency is half the vortex shedding one, there still appear interesting increases in lift and decreases in drag, therefore good performance parameters are to be found. The rest of the frequencies employed have a much smaller effect on the flow performance.

Table 4: Variation of wing performance when modifying non dimensional frequency and momentum coefficient. Maxima in performance increase arise when $F^+ = 1$. A significant drop can be seen when $F^+ > 1$.

Ψ	$C_\mu = 1 * 10^{-4}$	$C_\mu = 5 * 10^{-4}$	$C_\mu = 1 * 10^{-3}$	$C_\mu = 5 * 10^{-3}$	$C_\mu = 1 * 10^{-2}$
$F^+ = 0.1$	-6.6%	4%	16.8%	28.4%	26.7%
$F^+ = 0.5$	14.7%	28.1%	57.4%	68.5%	64.2%
$F^+ = 1.0$	66.9%	73%	80.3%	61.8%	50.8%
$F^+ = 5.0$	0.9%	-0.7%	-2.5%	1.4%	6.2%
$F^+ = 10.0$	0%	-0.1%	-0.8%	-4%	-5.1%

In order to visualize the advantages obtained when employing periodic forcing and using the optimum set of parameters, figure 4 compares the velocity distribution and pressure field around the NACA profile for the baseline case and for the optimum forcing conditions previously set. Clearly a drastic reduction of the number of vortices and its dimension is to be spotted whenever AFC is employed, notice as well that the pressure onto the upper side of the profile suffers an interesting reduction when periodic forcing is used.

4 Conclusions

A 2D-DNS simulation over the NACA 2412 profile at Re=6757 and for an angle of attack of 8° was undertaken. A baseline case was performed to obtain the natural vortex shedding flow, especially the natural vortex shedding frequency. The baseline case results were compared with the ones obtained when applying Active Flow Control and via periodic forcing. A set of five different frequencies and amplitudes were evaluated obtaining the optimum conditions required to maximize lift, minimize drag and to maximize the wing performance parameter. The optimum conditions were obtained whenever the forcing frequency was of the same order as the natural vortex shedding frequency. When maintaining the optimum forcing frequency and modifying the forcing amplitude, maximum lift, or minimum drag or maximum wing performance parameter could be obtained. Whenever the pulsating frequency employed was 50% of the natural one, the wing performance, lift increase and drag decrease were also quite relevant.

Abstract

This work focuses on the construction of various Padé approximants to conicality based Probabilistic Evolution Theory (PREVTH) solutions. PREVTH has been developed for conicality based explicit ODE(s) in Demiralp group studies in the last decade. Two classical particles system interacting via central forces has been taken as the targets. Paper is in conceptual level. Confirmative implementations will be given during the presentations in the conference.

Key words: PREVTH, Padé approximants, Two particle systems.

1 Introduction

A two particle system in Classical Mechanics has totally twelve unknown temporal function such that the positions of two particles in three dimensional physical Cartesian space can be described by totally six unknown temporally varying functions while the velocities of those two particles are also described by six temporally varying unknown functions. The motion's instances are defined by a single scalar independent variable, t, which is called "time". The equations of motion for this system is defined through equations amongst the partial derivative of a system function describing the total energy of the system. This function depends on position and momentum unknowns of the particles and does not change its explicit time dependence as long as the system is not under any external influence. The resulting equations are first order ODEs on the unknowns positions and momenta hence they are composed of twelve ODEs. Even though this may be considered quite complicated

 ISBN: 978-84-617-8694-7

the mass center positions and their relevant momentum unknowns (totally six unknowns) can be separated out as long as the other unknowns are organized as relative coordinates (the coordinates of one particle relative to the other). The equations of mass center describe the motion of a free particle under no external influence and they can be solved analytically. We do not intend to give those solutions and their interpretation.

Now by considering the following differences between positions as new relative position unknowns and by defining the following distance function to facilitate the analysis of relative motion

$$x_j(t) \equiv q_j(t) - q_{j+3}(t), \quad j = 1, 2, 3; \qquad r(t) \equiv \sqrt{x_1(t)^2 + x_2(t)^2 + x_3(t)^2} \tag{1}$$

we can construct the following equations of relative motion

$$\frac{dx_j(t)}{dt} = \frac{1}{\mu}\pi_j(t), \qquad \frac{d\pi_j(t)}{dt} = -V'\left(r(t)\right)\frac{x_j(t)}{r(t)}, \qquad j = 1, 2, 3 \tag{2}$$

where $1/\mu = 1/m_1 + 1/m_2$ and the relative positions and momenta are denoted by indexed $x(t)$ and $\pi(t)$s respectively. The Hamiltonian of the system characterized by relative motion can be given as follows

$$H\left(\boldsymbol{\pi}(t), r(t)\right) = \frac{1}{2\mu}\left(\pi_1(t)^2 + \pi_2(t)^2 + \pi_3(t)^2\right) + V\left(r(t)\right) \tag{3}$$

where V stands for the potential function of the considered system.

If the initial position and momentum vectors accompanying to (2) are linearly dependent then it is possible to prove that the solution vectors of (2) remain linearly dependent at every instant of the motion. In other words, the motion happens to limited on a straight line during the whole evolution including the initial moment. We do not intend to give further details for this case.

Abovementioned situation is a quite limited case. However, there is a more general issue dictating us that the system's motion happens to stay in the plane where the initial position and momentum vectors reside at the all time instances of the evolution. For this case we need to assume that the initial position and momentum vectors are linearly independent. We do not also intend to give further details of this issue since curios readers can get information even from some undergarduate textbooks.

Above analysis implies that the two particle system's motion can be described in the plane where the initial position and momentum vectors reside. This means there will be just four unknowns and four ODEs with appropriate initial conditions. We can write these planar equations of motions as follows

$$\begin{aligned}
&\frac{d\widetilde{x}_1}{dt}(t) = \frac{1}{\mu}\widetilde{\pi}_1(t), \qquad \widetilde{x}_1(0) = x_{0,1}, \qquad \frac{d\widetilde{\pi}_1}{dt}(t) = -\frac{V'\left(r(t)\right)}{r(t)}\widetilde{x}_1(t), \qquad \widetilde{\pi}_1(0) = \pi_{0,1} \\
&\frac{d\widetilde{x}_2}{dt}(t) = \frac{1}{\mu}\widetilde{\pi}_2(t), \qquad \widetilde{x}_2(0) = x_{0,2}, \qquad \frac{d\widetilde{\pi}_2}{dt}(t) = -\frac{V'\left(r(t)\right)}{r(t)}\widetilde{x}_1(t), \qquad \widetilde{\pi}_2(0) = \pi_{0,2}
\end{aligned} \tag{4}$$

 ISBN: 978-84-617-8694-7

$$r(t) = \sqrt{\widetilde{x}_1(t)^2 + \widetilde{x}_2(t)^2} \tag{5}$$

The sole dependence of the potential on a single distance function reminds us to use the circular (polar) coordinates. We can write

$$\widetilde{x}_1(t) = r(t)\cos\vartheta(t), \qquad \widetilde{x}_2(t) = r(t)\sin\vartheta(t) \tag{6}$$

$$r(t) = \sqrt{\widetilde{x}_1(t)^2 + \widetilde{x}_2(t)^2}, \qquad \vartheta(t) = \arctan\left(\frac{\widetilde{x}_2(t)}{\widetilde{x}_1(t)}\right) \tag{7}$$

$$\mathbf{e}_r(t) \equiv \frac{\nabla r(t)}{\|\nabla r(t)\|} = \begin{bmatrix} \cos\vartheta(t) \\ \sin\vartheta(t) \end{bmatrix}, \qquad \mathbf{e}_\vartheta(t) \equiv \frac{\nabla\vartheta(t)}{\|\nabla\vartheta(t)\|} = \begin{bmatrix} -\sin\vartheta(t) \\ \cos\vartheta(t) \end{bmatrix} \tag{8}$$

The new defined unit vectors vary in time so they have non-vanishing temporal derivatives. We can write,

$$\frac{d\mathbf{e}_r(t)}{dt} = \vartheta'(t)\mathbf{e}_\vartheta(t), \qquad \frac{d\mathbf{e}_\vartheta(t)}{dt} = -\vartheta'(t)\mathbf{e}_r(t) \tag{9}$$

The angular momentum square can be written as follows,

$$\|\widetilde{\mathbf{x}}(t) \times \widetilde{\boldsymbol{\pi}}(t)\|^2 = \mu\left(1 + \tan\vartheta(t)^2\right) r(t)^2\cos\vartheta(t)^2\vartheta'(t) = \mu r(t)^2\vartheta'(t) \tag{10}$$

$$p_\vartheta(t) \equiv \mu r(t)^2\vartheta'(t) \equiv \mu c_1 \tag{11}$$

where we have used the angular momentum conservation law.

We do not intend to get into the further details of angular momentum issue. However, we can use the angular momentum conservation law here in construction of the equations of motion in circular motion. Now we can write all the equations of unknowns as follows.

$$r'(t) = \frac{p_r(t)}{\mu}, \qquad r(0) = r_0 \tag{12}$$

$$p_r'(t) = \mu r(t)\vartheta'(t)^2 - V'(r(t)), \qquad p_r(0) = p_{r,0} \tag{13}$$

$$\vartheta'(t) = \frac{c_1}{r(t)^2}, \qquad \vartheta(0) = \vartheta_0 \tag{14}$$

$$p_\vartheta' = 0, \qquad p_\vartheta(0) = \mu c_1 \tag{15}$$

 ISBN: 978-84-617-8694-7

Radial momentum and angular momentum give us the below equations.

$$r'(t) = \frac{p_r(t)}{\mu}, \qquad r(0) = r_0 \tag{16}$$

$$p_r'(t) = \frac{\mu c_1^2}{r(t)^3} - V'(r(t)), \qquad p_r(0) = p_{r,0} \tag{17}$$

$$\vartheta'(t) = \frac{c_1}{r(t)^2}, \qquad \vartheta(0) = \vartheta_0 \tag{18}$$

$$p_\vartheta' = 0, \qquad p_\vartheta(0) = \mu c_1 \tag{19}$$

We need to solve these equations. To do so we take certain elimination steps and get

$$\frac{dr}{dt} = \pm\sqrt{\frac{2}{\mu}}\sqrt{E - \frac{\mu c_1^2}{2}\frac{1}{r^2} - V(r)} \tag{20}$$

This can be solved by using certain well known approaches as long as the structure of the potential permits us. We do not intend to give further details since they are well known for someones having sufficiently strong background.

On the other hand, instead of the solution of this equation one can seek a relation between the polar coordinate evolutions. We can give the result without repeating the derivation stages of the trajectory as follows

$$\frac{1}{r(\vartheta)} = \left(\frac{1}{r_0} - \frac{\nu}{\mu c_1^2}\right)\cos(\vartheta - \vartheta_0) - \frac{p_{r,0}}{\mu c_1}\sin(\vartheta - \vartheta_0) + \frac{\nu}{\mu c_1^2} \tag{21}$$

where the function $V(r)$ has been specified as the potential function of a system interacted via a central force. Hence we have used the equality $V(r) = -\nu/r$ where ν is the product of the system particles' masses and univariate gravitational constant ($\nu \equiv gm_1m_2$). All entities having a zero in their indices correspond to an initial value. c_1 is the constant specifying angular momentum conservation while μ stands for the previously defined reduced mass of the two particles system.

This formula can be put into more amenable form by defining

$$\overline{c} \equiv \frac{\nu}{\mu c_1^2}, \qquad 1 - \frac{\mu c_1^2}{\nu r_0} \equiv \varepsilon\cos\phi, \qquad \frac{c_1 p_{r,0}}{\nu} \equiv \varepsilon\sin\phi \tag{22}$$

and writing

$$\varepsilon = \sqrt{\left(1 - \frac{\mu c_1^2}{\nu r_0}\right)^2 + \frac{c_1^2 p_{r,0}^2}{\nu^2}}, \qquad \phi = \tan^{-1}\left(\frac{c_1 p_{r,0} r_0}{\nu r_0 - \mu c_1^2}\right) \tag{23}$$

 ISBN: 978-84-617-8694-7

By using these definitions, we can rewrite circular motion trajectory in a more simple (compact) form as follows.

$$\frac{1}{r\left(\vartheta\right)} = \overline{c}\left[\,1 - \varepsilon\cos\left(\vartheta - \vartheta_0 - \phi\right)\right] \tag{24}$$

In this formula ε is expected to be positive without exceeding 1. This means that the following inequalities hold

$$\varepsilon \leq 1 \Longrightarrow \varepsilon^2 \leq 1 \implies \left(1 - \frac{\mu c_1^2}{\nu r_0}\right)^2 + \frac{c_1^2 p_{r,0}^2}{\nu^2} \leq 1 \Longrightarrow \frac{\mu^2 c_1^2}{\nu^2 r_0^2} - \left(\frac{2\mu}{\nu r_0} - \frac{p_{r,0}^2}{\nu^2}\right) \leq 0 \tag{25}$$

$$-\sqrt{2 - \frac{r_0 p_{r,0}^2}{\mu\nu}} \leq c_1 \leq \sqrt{2 - \frac{r_0 p_{r,0}^2}{\mu\nu}} \Longrightarrow -\sqrt{2\mu^2 - \frac{\mu r_0 p_{r,0}^2}{\nu}} \leq p_{\vartheta,0} \leq \sqrt{2\mu^2 - \frac{\mu r_0 p_{r,0}^2}{\nu}} \tag{26}$$

We find this level of recalling information sufficient for this moment.

2 Constructing Probabilistic Evolution Theory Equations (PREVTH)

Now we take the following two ODEs as the target of PREVTH

$$\begin{aligned} r'(t) &= \frac{p_r(t)}{\mu}, \qquad r(0) = r_0 \\ p_r'(t) &= \frac{p_{\vartheta,0}^2}{\mu}\frac{1}{r(t)^3} - \frac{\nu}{r(t)^2}, \qquad p_r(0) = p_{r,0} \end{aligned} \tag{27}$$

Even though PREVTH expects conicality (second degree multinomiality) at the right hand side of target ODEs [8], these ODEs do not have such type of right hand sides. However it is possible to use space extension [5–7] herein.

$$u_1(t) \equiv \frac{1}{r(t)}, \quad u_2(t) \equiv \frac{1}{r(t)^2}, \quad u_3(t) \equiv \frac{p_r(t)}{r(t)}, \quad u_4(t) \equiv p_r(t)^2 \tag{28}$$

These new unknowns are added to two original ODEs one by one. First we add $u_1(t)$ as a new unknown temporal function. This addition realized by starting with the differentiation of both sides of first equation in (28) this gives an ODE whose right hand side contains the first derivative of previously existing unknown function $r(t)$. This derivative can be replaced by its equivalent in the previously existing ODE for $r(t)$. This replacement enables us to get a right hand side depending on $r(t)$, $p_r(t)$, $u_1(t)$. However conicality still has not been obtained and urges us to define the new additional unknown $u_2(t)$. Then $u_2(t)$ can be

similarly added to the obtained three ODEs for $r(t)$, $p_r(t)$, $u_1(t)$. The right hand sides of the obtained four ODEs for $r(t)$, $p_r(t)$, $u_1(t)$, $u_2(t)$ still do not have conicality. This urges us to continue in the same way for adding $u_3(t)$ and finally $u_4(t)$. At that addition (space extension) we arrive at

$$\begin{array}{ll}
r'(t) = \frac{1}{\mu} p_r(t), & r(0) = r_0 \\
p_r'(t) = \frac{p_{\vartheta,0}^2}{\mu} u_1(t) u_2(t) - \nu u_2(t), & p_r(0) = p_{r,0} \\
u_1'(t) = -\frac{1}{\mu} u_2(t) p_r(t), & u_1(0) = \frac{1}{r_0} \\
u_2'(t) = -\frac{2}{\mu} u_2(t) u_3(t), & u_2(0) = \frac{1}{r_0^2} \\
u_3'(t) = -\frac{1}{\mu} u_2(t) u_4(t) + \frac{1}{\mu} p_{\vartheta,0}^2 u_2(t)^2 + \nu u_1(t) u_2(t), & u_3(0) = \frac{p_{r,0}}{r_0} \\
u_4'(t) = \frac{2 p_{\vartheta,0}^2}{\mu} u_2(t) u_3(t) - 2\nu u_1(t) u_3(t), & u_4(0) = p_r^2
\end{array} \tag{29}$$

which are in conical structure and appropriate for the application of PREVTH [9]. We can now rewrite these equations in the following concise form

$$\dot{\mathbf{x}}(t) = \mathbf{F}_0 + \mathbf{F}_1 \mathbf{x}(t) + \mathbf{F}_2 \mathbf{x}(t)^{\otimes 2} \tag{30}$$

where

$$\mathbf{x}(t) = \left[\, r(t) \;\; p_r(t) \;\; u_1(t) \;\; u_2(t) \;\; u_3(t) \;\; u_4(t) \, \right]^T \tag{31}$$

For our two particle system $\mathbf{F}_0 = \mathbf{0}_6$ and $\mathbf{F}_1$ is composed of two outer products from six dimensional Cartesian space standard unit vectors while $\mathbf{F}_2$ is a rectangular matrix of 6×36 type. We do not intend to present the structure of $\mathbf{F}_2$ explicitly since we do not find it necessary.

3 Constancy Adding Space Extension (CASE)

The conical structure obtained in the previous section is not the ultimate form on which PREVTH is applied. The desired form is again conical but the constant vector is desired to be vanished while the desired form of linear term coefficient is proportional to the identity matrix whose number of rows and columns is identical to the element number of the system vector. These desired forms can be produced by using very specific Constancy Adding Space Extension (CASE) which adds just a constant function as a new unknown. We can write the following equalities

$$\mathbf{x}_{aug}(t) \equiv \left[\, \mathbf{x}(t)^T \;\; a \, \right]^T, \qquad \mathbf{x}_{aug}(t)^{\otimes 2} = \mathbf{P}^{-1} \left[\mathbf{x}^{\otimes 2^T} \;\; a\mathbf{x}^T \;\; a\mathbf{x}^T \;\; a^2 \right]^T \tag{32}$$

where the unitary matrix $\mathbf{P}$ stands for an appropriate permutation matrix of 49×49. These equalities are desired to take us to the following ODEs with specific conicality

$$\dot{\mathbf{x}}_{aug}(t) = \beta \mathbf{x}_{aug} + \mathbf{F}_{aug} \mathbf{x}_{aug}^{\otimes 2} = \beta \mathbf{x}_{aug} + \mathbf{G} \left[\mathbf{x}^{\otimes 2^T} \;\; a\mathbf{x}^T \;\; a\mathbf{x}^T \;\; a^2 \right]^T, \qquad \mathbf{G} \equiv \mathbf{F}_{aug} \mathbf{P}^{-1} \tag{33}$$

 ISBN: 978-84-617-8694-7

where β stands for a scalar which is arbitrary at this moment while augmented rectangular matrices, $\mathbf{F}_{aug}$, and $\mathbf{G}$, denote 7×49 type. $\mathbf{G}$'s blocks in the partitioning in accordance with the Kronecker square of the augmented system vector, $\mathbf{x}^{\otimes 2}$ should have the following equivalents to get harmony with the CASE

$$\begin{aligned} &\mathbf{G}_{1,1} \equiv \mathbf{F}_2, \qquad \beta \mathbf{I}_6 + a\mathbf{G}_{1,2} + a\mathbf{G}_{1,3} = \mathbf{F}_1, \qquad \mathbf{G}_{1,4} = \frac{1}{a^2}\mathbf{F}_0 \\ &\mathbf{G}_{2,1} = \mathbf{G}_{2,2} = \mathbf{G}_{2,3} = 0, \qquad G_{2,4} = \frac{\beta}{a} \end{aligned} \tag{34}$$

4 Kronecker Power Series Solution via Probabilistic Evolution Theory (PREVTH)

The first part of (33) can be solved by the following Kronecker power series

$$\mathbf{x}_{aug}(t) = \mathrm{e}^{\beta t} \sum_{j=0}^{\infty} \frac{u^j}{j!} \mathbf{T}_j \mathbf{a}^{\otimes (j+1)} \tag{35}$$

where $\mathbf{T}_j$ stands for the jth Telescope Matrix which is defined as the product of some Monocular Matrices in the following equalities

$$\mathbf{T}_j \equiv \prod_{k=1} \mathbf{M}_k, \qquad \mathbf{M}_k \equiv \sum_{\ell=0}^{k-1} \mathbf{I}_7^{\otimes \ell} \otimes \mathbf{F} \otimes \mathbf{I}^{\otimes (k-1-\ell)} \tag{36}$$

In the above Kronecker power solution the initial vector has been symbolized by $\mathbf{a}$. That Kronecker power solution can be reexpressed as follows

$$\mathbf{x}_{aug}(t) = \mathrm{e}^{\beta t} \sum_{j=0}^{\infty} \frac{u^j}{j!} \mathbf{v}_j(\mathbf{a}), \quad \mathbf{v}_j(\mathbf{a}) \equiv \mathbf{T}_j \mathbf{a}^{\otimes j} \tag{37}$$

where the vectors, $\mathbf{v}_j(\mathbf{a})$s, satisfy the following recursion as we have recently proven.

$$\mathbf{v}_j(\mathbf{a}) = \sum_{k=0}^{j-1} \binom{j-1}{k} \lfloor \mathbf{F}_{aug}, \mathbf{v}_k \rceil \mathbf{v}_{j-k-1}, \quad j = 1, 2, 3, ...; \quad \mathbf{v}_0(\mathbf{a}) = \mathbf{a} \tag{38}$$

where we have used the squarification and SquTelMat concepts which are defined through the following equalities

$$\mathbf{F} \equiv \left[\mathbf{F}^{(1)} \quad ... \quad \mathbf{F}^{(n+1)}, \right], \qquad \lfloor \mathbf{F}, \boldsymbol{\xi}_k \rceil = \sum_{i=1}^{n+1} \left(\mathbf{e}_i^T \boldsymbol{\xi}_k \right) \mathbf{F}^{(i)} \tag{39}$$

 ISBN: 978-84-617-8694-7

where a linear combination of the square blocks is formed using the vector elements as coefficients. Now, truncations from (37) may be used in order to approximate the solution of the initial value problem.

After the Constancy Adding Space Extension (CASE) application we have told above, we obtain the non-zero elements of $\mathbf{F}_{aug}$ as follows

$$\begin{aligned}\mathbf{F}_{aug} &= \frac{1}{2}\mathbf{e}_1\mathbf{e}_{28}^T + \frac{1}{2}\mathbf{e}_1\mathbf{e}_{46}^T - \frac{1}{2}\mathbf{e}_2\mathbf{e}_{18}^T - \frac{1}{2}\mathbf{e}_2\mathbf{e}_{24}^T - \mathbf{e}_3\mathbf{e}_{20}^T - \mathbf{e}_3\mathbf{e}_{38}^T + \frac{1}{2}\mathbf{e}_4\mathbf{e}_{10}^T + \frac{1}{2}\mathbf{e}_4\mathbf{e}_{16}^T \\ &\quad -\mathbf{e}_4\mathbf{e}_{18}^T - \mathbf{e}_4\mathbf{e}_{24}^T - 2\mathbf{e}_5\mathbf{e}_{19}^T + \mathbf{e}_5\mathbf{e}_{20}^T - 2\mathbf{e}_5\mathbf{e}_{31}^T + \mathbf{e}_5\mathbf{e}_{38}^T + \mathbf{e}_6\mathbf{e}_{17}^T - \frac{1}{2}\mathbf{e}_6\mathbf{e}_{19}^T \\ &\quad -\mathbf{e}_6\mathbf{e}_{20}^T - \mathbf{e}_6\mathbf{e}_{31}^T \end{aligned} \tag{40}$$

5 Padé Approximants of PREVTH Solution Components

The main purpose of this paper is to construct Certain Padé approximants to the PREVTH solutions mentioned in the previous section. There are various alternatives to construct Padé approximants: (i) Each element of PREVTH solution vector can be individually approximated by certain Padé approximants; (ii) The norm of the PREVTH vector solution can be Padé approximated as a whole approximations; (iii) The inner product of the PREVTH solution vector with another given (mostly constant) vector can also Padé approximated. The examples can be populated as desired.

We do not give any detail for the Padé approximant construction since it is a quite well-known issue. Beyond that we do not intend to give any symbolical or numerical results even though we have results of many implementation for confirmative purposes. This is because of the time and paper size limitations. We are going to realize a sufficiently comprehensive implementative during the presentation. However, we can now say that the results are very parallel to what we have expected in the convergence properties.

6 Concluding Remarks

As we can see from the last equation, after applying PREVTH, we have 6 ODEs which have at most second degree multinomials on the right hand side and these are all solvable. In this work, we have shown that the structure of the two particles celestial mechanical systems allow us to apply Probabilistic Evolution Theory(PREVTH). We are going to give more plots and implementation during our presentation in the conference. In the main part sections of this paper we have taken β as zero. This is because the norm suppression produces zero value for β. The other important point is the existence of just a single position variable (radial variable) at then. This facilitates the analysis pretty much.

Abstract

The aim of this paper is to verify the positive definiteness for real symmetric matrices. An excellent method for generating computer-assisted proofs of the positive definiteness was proposed by Rump. In this paper, we propose verification methods using computed Cholesky factors and their approximate inverse matrices. Positive definiteness can be verified for a wide range of problems by the proposed method.

Key words: computer-assisted proof, positive definiteness, numerical liner algebra
MSC 2000: 65F15, 65G50

1 Introduction and Preceding Study

The aim of this paper is to verify the positive definiteness for real symmetric matrices. A verification method has already been proposed by Rump [2]. The Rump's method is quick and but can fail to verify positive definiteness when the condition number of the given matrix is high. Herein, we propose verification methods for positive definiteness that work large scale or ill-conditioned matrices.

Here, we introduce the notation used in this paper and briefly review Rump's method [2]. Let $\mathbb{F}$ be the set of floating-point numbers as defined by the IEEE Std. 754 [1]. $fl(\cdot), fl_{\bigtriangledown}(\cdot)$ and $fl_{\bigtriangleup}(\cdot)$ indicate that all operations inside the parentheses are evaluated using floating-point arithmetic with rounding to the nearest, rounding downward and upward mode, respectively. For simplicity, we assume that neither overflow nor underflow occurs in $fl(\cdot)$ because underflow can be handled by adding a constant to the arguments presented in this paper. Let u be the unit roundoff, e.g. $u = 2^{-53}$ for binary64 in the IEEE standard. For

 ISBN: 978-84-617-8694-7

$x, y \in \mathbb{R}^n$, the notation $|x|$ is defined $|x| = (|x_1|, |x_2|, \ldots, |x_n|)^T$ and $x < y$ means $x_i < y_i$ for all i. This notation can be extended to matrices in a straightforward manner.

Let $\bar{\rho} = fl_{\triangle}(\sum_{j=1}^{n} \gamma_{j+1} a_{jj})$, $\gamma_n = nu/(1-nu)$, $nu < 1$ and $B = fl_{\triangledown}(A - \bar{\rho} I)$, where I is the identity matrix. Rump showed that if Cholesky decomposition for the matrix B can be successfully computed using numerical computation, the matrix A is positive definite. We call this method T0.

2 The Proposed Method

In this section, we first introduce lemmas concerning residuals, eigenvalues and norms.

Lemma 1 (Theorem 4.4 in [3]) *Let $A = A^T \in \mathbb{F}^{n\times n}$ and assume that Cholesky decomposition has been successfully completed using numerical computation. Then*

$$\hat{R}^T \hat{R} - A = \Delta A, \quad |\Delta A| \leq (n+1)u|\hat{R}|^T|\hat{R}|, \tag{1}$$

is satisfied, where $\hat{R} \in \mathbb{F}^{n\times n}$ is a factor computed by Cholesky decomposition.

Lemma 2 (Corollary 8.1.6 in [4]) *If A and $A+E$ are n-by-n symmetric matrices, then*

$$|\lambda_k(A+E) - \lambda_k(A)| \leq ||E||_2$$

for $1 \leq k \leq n$, where $\lambda_k(A)$ denotes the kth eigenvalue of the matrix A.

Lemma 3 (Lemma 2.3.3 in [4]) *If $F \in \mathbb{R}^{n\times n}$ and $||F|| < 1$, then $I+F$ is nonsingular and*

$$||(I-F)^{-1}|| \leq \frac{1}{1-||F||}.$$

Next, we propose a theorem that places a lower bound on the minimum eigenvalue.

Theorem 4 *Let $A = A^T$ and introduce $\hat{R}$ and $\hat{X} \in \mathbb{R}^{n\times n}$. Set $\Delta X := \hat{X}\hat{R} - I \in \mathbb{R}^{n\times n}$. If there exist matrices $\hat{R}$ and $\hat{X}$ such that $||\Delta X||_2 < 1$, then*

$$\lambda_{\min}(A) \geq \frac{(1-||\Delta X||_2)^2}{||\hat{X}\hat{X}^T||_2} - ||\Delta A||_2 \quad \textit{where} \quad \Delta A = \hat{R}^T\hat{R} - A. \tag{2}$$

Proof. From Lemma 2, we obtain

$$\lambda_{\min}(A) \geq \lambda_{\min}(\hat{R}^T\hat{R}) - ||\Delta A||_2 = ||(\hat{R}^T\hat{R})^{-1}||_2^{-1} - ||\Delta A||_2. \tag{3}$$

From the assumption $||\Delta X||_2 < 1$ and Lemma 3, $\hat{R}$ and $I + \Delta X$ are nonsingular and we obtain

$$\hat{R}^{-1}\hat{R}^{-T} \;=\; (I+\Delta X)^{-1}\hat{X}\hat{X}^T(I+(\Delta X)^T)^{-1}.$$

 ISBN: 978-84-617-8694-7

From this and Lemma 3, we can derive

$$||(\hat{R}^T\hat{R})^{-1}||_2 \leq \frac{||\hat{X}\hat{X}^T||_2}{(1-||\Delta X||_2)^2}. \tag{4}$$

We obtain (2) by substituting (4) into (3). □

We set $\hat{R}$ and $\hat{X}$ to be the computed Cholesky factors and an approximate inverse matrix of $\hat{R}$, respectively. The computational cost of calculating $\hat{R}$ and $\hat{X}$ is $\frac{1}{3}n^3 + O(n^2)$ flops.

We will prove $\lambda_{\min}(A) > 0$ by computing the upper bounds for $||\hat{X}\hat{X}^T||_2$ and $||\Delta A||_2$ in Theorem 4. First, we propose a fast method (T1). If $S = S^T \in \mathbb{R}^{n\times n}$, then $||S||_2 \leq ||S||_\infty$. The norm $||S||_\infty$ can be computed as follows:

$$||S||_\infty = ||\ |S|e\ ||_\infty, \quad e = (1, 1, \dots 1)^T \in \mathbb{F}^n. \tag{5}$$

We can obtain upper bounds for $||\hat{X}\hat{X}^T||_2$ and $||\Delta A||_2$ as follows:

$$||\hat{X}\hat{X}^T||_2 \leq fl_\triangle(||\ |\hat{X}|(|\hat{X}^T|e)||_\infty), \quad ||\Delta A||_2 \leq fl_\triangle((n+1)u||\ |\hat{R}^T|(|\hat{R}|e)||_\infty). \tag{6}$$

The total cost of proving $\lambda_{\min}(A) > 0$ is thus $\frac{2}{3}n^3 + O(n^2)$ flops.

Next, we introduce methods that use the enclosure property of matrix multiplication. Upper bounds for $||\hat{X}\hat{X}^T||_2$ and $||\Delta A||_2$ can be obtained as follows:

$$||\hat{X}\hat{X}^T||_2 \leq ||\max(|fl_\triangledown(\hat{X}\hat{X}^T)|, |fl_\triangle(\hat{X}\hat{X}^T)|)||_\infty, \tag{7}$$

$$||\Delta A||_2 \leq ||\max(|fl_\triangledown(\hat{R}^T\hat{R} - A)|, |fl_\triangle(\hat{R}^T\hat{R} - A)|)||_\infty. \tag{8}$$

The computational cost of calculating $\hat{X}\hat{X}^T$ and $\hat{R}^T\hat{R}$ is $\frac{1}{4}n^3 + O(n^2)$ flops, because $\hat{X}$ and $\hat{R}$ are triangular matrices, and $\hat{X}\hat{X}^T$ and $\hat{R}^T\hat{R}$ are symmetric. The computational cost of (7) and (8) is $\frac{1}{2}n^3 + O(n^2)$ flops. We now define methods T2, T3 and T4:

- T2: (7) and (6) are used as upper bounds for $||\hat{X}^T\hat{X}||_\infty$ and $||\Delta A||_\infty$.
- T3: (6) and (8) are used as upper bounds for $||\hat{X}^T\hat{X}||_\infty$ and $||\Delta A||_\infty$.
- T4: (7) and (8) are used as upper bounds for $||\hat{X}^T\hat{X}||_\infty$ and $||\Delta A||_\infty$.

The norm $||\Delta X||_2$ can be bounded as follows:

$$|\Delta X| \leq nu|\hat{X}||\hat{R}|, \quad ||\Delta X||_2 \leq \sqrt{||\Delta X||_1||\Delta X||_\infty}.$$

This computational cost of this is $O(n^2)$ flops using (5).

Table 1 shows the computational cost for these norms using each method. The cost of Cholesky decomposition is normalised to one in the Ratio column, in other words, the

T4	$n^3/2 + O(n^2)$	$n^3/2 + O(n^2)$	5

cost of T0 is defined to be one. Next, we check that positive definiteness is guaranteed for more ill-conditioned matrices using our methods. Let $A = A^T \in \mathbb{F}^{n\times n}$. The matrix A was generated in MATLAB by $A =$ `gallery('randsvd'`$, n, -c, 3, n, n, 1)$, where c is the expected condition number of A. Table 2 shows the maximum condition number c for each method. The methods could verify the positive definiteness up to these condition numbers. These numerical results indicate that our methods can cover more ill-conditioned matrices.

Table 2: The maximum condition numbers for which each method can verify the positive definiteness of matrices of size n

n	T0	T1	T2	T3	T4

Abstract

Inversion of infinite invertible unreduced Hessenberg matrices has been studied in [1], with applications to infinite invertible unreduced tridiagonal matrices. The case of infinite invertible reduced Hessenberg matrices and infinite reduced tridiagonal matrices, when the number of zeros on the subdiagonal is finite or infinite, is now studied for a complete landscape of inversion of such matrices. Reduced Hessenberg matrices are regarded finally as bounded linear operators

Key words: Hessenberg matrix, tridiagonal matrix, inverse matrix, reduced matrix.

1 Introduction

A characterization of the finite nonsingular unreduced Hessenberg matrices is related with the distinguished rank structure of their inverse matrix [2, 3, 4]. The inverses of such matrices are rank one perturbation, $UV + T$, of triangular matrices. The inverses of real or complex infinite Hessenberg matrices have a similar structure and the method for inverting infinite Hessenberg matrices is based on the structure properties. In particular, classical inverses of general tridiagonal matrices can be generated through recurrence relations.

Some background about inversion of infinite matrices and their applications can be found in the literature; see e.g. [5, 6] and the references given there. Hessenberg matrices appears in signal processing, time series, birth-dead processes and orthogonal polynomial as matrix representation of the multiplication by z operator. They arise in numerical linear algebra, as a result of the application of Givens or Householder orthogonal transformations for a general matrix, when solving the eigenvalue problem.

In this paper we present the inversion of infinite invertible reduced Hessenberg matrices and the inversion of infinite invertible reduced tridiagonal, as particular case, when the number of zeros in subdiagonal is finite or infinite. Finally, reduced Hessenberg matrices are regarded as bounded linear operator in a Hilbert space.

The material is organized as follow. In Section 1, we recall some basic result about inverses of finite Hessenberg matrices and infinite unreduced Hessenberg matrices and tridiagonal matrices. In Section 2 we study the inversion of infinite reduced Hessenberg matrices when the number of zeros in subdiagonal is finite and infinite. Section 3 contains a short remark regarding the inversion of bounded linear operators. Some illustrative examples are also given.

1.1 Unreduced Hessenberg matrices of finite order

We recall some lemmas related with finite upper Hessenberg matrices and tridiagonal matrices. A matrix $H = (h_{ij})_{i,j=1}^{n}$ is upper Hessenberg if its elements h_{ij} satisfy $h_{ij} = 0$ for $i \geq j + 2$. We also recall that an order n Hessenberg matrix H is an unreduced upper Hessenberg matrix if it has nonzero subdiagonal entries, $h_{i+1,i} \neq 0$, $i = 1, 2, ..., n - 1$. Next lemma is well-known, [1, 2, 3].

Lemma 1. *A nonsingular matrix $H = (h_{ij})_{i,j=1}^{n}$ is unreduced upper Hessenberg if and only if its inverse matrix has the structure $B = UV + T$, being U a column matrix with nonzero n-th component, V is a row matrix with nonzero 1-st component. T is strictly upper triangular having null entries on its main diagonal and nonzero entries on the superdiagonal, $t_{i,i+1} = \frac{1}{h_{i+1,i}} \neq 0, 1 \leq i \leq n - 1$.*

Some numerical methods for inverting finite Hessenberg matrices and tridiagonal matrices are available, see e.g. [2, 7, 8, 9] and references given there.

1.2 Reduced Hessenberg matrices of finite order

If we have a nonsingular upper Hessenberg matrix having a zero entry on the subdiagonal, we can decompose the matrix in blocks and using the Schur complement. For a nonsingular reduced Hessenberg matrix H with $h_{k+1,k} = 0$, we consider

$$H = \left(\begin{array}{c|c} H_{11} & H_{12} \\ \hline 0 & H_{22} \end{array}\right) \qquad \text{and} \qquad B = \left(\begin{array}{c|c} B_{11} & B_{12} \\ \hline 0 & B_{22} \end{array}\right),$$

where $B_{11} = H_{11}^{-1}$, $B_{22} = H_{22}^{-1}$ and $B_{12} = -B_{11}H_{12}B_{22}$. The matrix B is the inverse of H and both matrices have the same block upper triangular structure.

If matrix H is a nonsingular upper Hessenberg matrix having a finite number of zero entries on the subdiagonal, we can to proceed in the same way.

 ISBN: 978-84-617-8694-7

1.3 Inverses of infinite unreduced Hessenberg matrices

Given a real or complex infinite-dimensional matrix $A = (a_{ij})$, the matrix $B = (b_{ij})$ is a classical inverse of A if both matrices A and B satisfy $AB = BA = I$, with I the identity matrix. The matrix A may have (or may not have) classical inverse. Alternatively, A may have two classical inverses, and then infinitely many classical inverses; see e.g. [1, 6, 10].

An infinite matrix $H = (h_{ij})$ is an upper Hessenberg matrix if $h_{ij} = 0$ for $i \geq j + 2$. An infinite Hessenberg matrix H is an unreduced upper Hessenberg matrix if its subdiagonal entries are nonzero, $h_{i+1,i} \neq 0$, and $i = 1, 2, ...$

Conditions for an infinite invertible matrix H be an unreduced Hessenberg matrix are given in Corollary 1 of [1], that we recall below as Lemma 2, and applications to unreduced tridiagonal matrices. The submatrix H_n is the left principal one of order n. The submatrix $H^{(i)}_{n-i}$ is the right principal one of order $n - i$, which begins in the $i + 1$-th row and column and finishes in the n-th row and column.

Lemma 2. *Let $H = (h_{ij})$ be an infinite invertible matrix and assume that the limits*

$$\lim_n \frac{|H^{(i)}_{n-i}|}{|H_n|} = \xi_i,$$

for $i \geq 1$ are finite and nonzero. Then H is an unreduced upper Hessenberg matrix if and only if its classical inverse matrix $B = (b_{ij})$ has the form $B = UV + T$, where $U = (u_1, u_2, ...)^T$ is a column vector with nonzero components, $V = (v_1, v_2, ...)$ is a row vector with nonzero first component, and T is strictly upper triangular, having zeros on its main diagonal, and nonzero entries $t_{i,i+1} = h^{-1}_{i+1,i}$, $i \geq 1$, on its superdiagonal.

2 Inverses of infinite reduced Hessenberg matrices

2.1 Infinite reduced Hessenberg matrices with a finite number of zeros in the subdiagonal

When an infinite reduced Hessenberg matrix H has at least a null entry on its subdiagonal, we can evaluate its classical inverse in a similar way as the known method of the Schur complement for a matrix of finite order.

Proposition 1. *Let H be an infinite invertible upper Hessenberg matrix with only a zero entry on its subdiagonal. Then, its classical inverse matrix can be calculate using a block matrix procedure. If H is*

$$H = \left(\begin{array}{c|c} H_{11} & H_{12} \\ \hline 0 & H_{22} \end{array} \right),$$

 ISBN: 978-84-617-8694-7

a classical inverse matrix is

$$B = \left(\begin{array}{c|c} H_{11}^{-1} & -H_{11}^{-1} H_{12} H_{22}^{-1} \\ \hline 0 & H_{22}^{-1} \end{array} \right),$$

where H_{11} is a finite nonsingular unreduced upper Hessenberg matrix, H_{22} is an infinite invertible unreduced upper Hessenberg matrix. There are infinitely many classical inverses of H.

Proof. As H_{11} is a finite matrix and H_{12} has a finite number of rows, products satisfy the associative property and products HB and BH give obviously I. □

The case of finitely many zeros on the subdiagonal follows from the previous Proposition.

Proposition 2. *Let H be an infinite invertible upper Hessenberg matrix with a finite number of zero entries on the subdiagonal. Then its classical inverse matrices can be obtained using a block matrix procedure in a similar way as Proposition 1.*

Proof. We consider the block matrix

$$H = \left(\begin{array}{c|c} H_{11} & H_{12} \\ \hline 0 & H_{22} \end{array} \right),$$

where all zero entries in the subdiagonal are in H_{11}. The inverse of the finite matrix H_{11} is given in Subsection 1.2. Then H_{22} is an unreduced Hessenberg matrix and the inverse of matrix H is given by the formula of Proposition 1. □

Obviously, H has infinitely many classical inverses because H_{22} is an unreduced infinite Hessenberg matrix and, by Proposition 1, has infinitely many classical inverses.

Example 1. *The next matrix H has zero entries in $h_{23} = h_{54} = h_{76}$ and nonzero in all other entries on its subdiagonal. Its inverse matrix is B :*

$$H = \left(\begin{array}{cc|cc|cc|c} 1 & 0 & 1 & 0 & 1 & 0 & \\ 1 & 1 & 0 & 1 & 0 & 1 & H_{14} \\ \hline & & 1 & 0 & 1 & 0 & \\ & & 1 & 1 & 0 & 1 & H_{24} \\ \hline & & & & 1 & 0 & \\ & & & & 1 & 1 & H_{34} \\ \hline & & & & & & H_{44} \end{array} \right), \; B = \left(\begin{array}{cc|cc|cc|c} 1 & 0 & & & & & \\ -1 & 1 & B_{12} & & B_{13} & & B_{14} \\ \hline & & 1 & 0 & & & \\ & & -1 & 1 & B_{23} & & B_{24} \\ \hline & & & & 1 & 0 & \\ & & & & -1 & 1 & B_{34} \\ \hline & & & & & & B_{44} \end{array} \right),$$

 ISBN: 978-84-617-8694-7

where $B_{44}=H_{44}^{-1}$ *and*

$$\begin{aligned}
B_{12} &= -H_{11}^{-1}H_{12}H_{22}^{-1}=-\begin{pmatrix}1&0\\-1&1\end{pmatrix}\begin{pmatrix}1&0\\0&1\end{pmatrix}\begin{pmatrix}1&0\\-1&1\end{pmatrix}=\begin{pmatrix}-1&0\\2&-1\end{pmatrix},\\
B_{23} &= -H_{22}^{-1}H_{23}H_{33}^{-1}=-\begin{pmatrix}1&0\\-1&1\end{pmatrix}\begin{pmatrix}1&0\\0&1\end{pmatrix}\begin{pmatrix}1&0\\-1&1\end{pmatrix}=\begin{pmatrix}-1&0\\2&1\end{pmatrix},\\
B_{13} &= -H_{11}^{-1}(H_{13}-H_{12}H_{22}^{-1}H_{23})H_{33}^{-1},\\
B_{34} &= -H_{33}^{-1}H_{34}H_{44}^{-1},\\
B_{24} &= -H_{22}^{-1}(H_{24}-H_{23}H_{33}^{-1}H_{34})H_{44}^{-1},\\
B_{14} &= -H_{11}^{-1}(H_{14}-H_{13}H_{33}^{-1}H_{34}-H_{12}H_{22}^{-1}[H_{24}-H_{23}H_{33}^{-1}H_{34}])H_{44}^{-1}.
\end{aligned}$$

Different blocks can be obtained in each block-column from diagonal to top. A general formula for B_{ij} is shown in next theorem. We observe that H_{44} is unreduced and then it has not a unique inverse matrix.

The case of infinitely many zeros on the subdiagonal of H is a little different and is studied in next subsection.

2.2 Inverses of infinite Hessenberg matrices with an infinite number of zeros in the subdiagonal

Theorem 1. *A reduced invertible upper Hessenberg matrix* $H=(h_{ij})$ *with infinitely many zeros on its subdiagonal can be decomposed in infinite nonsingular blocks and the inverse matrix* $B=(b_{ij})$ *has the same block structure in a similar way to the finite case. The classical inverse matrix is unique. Different blocks of* B *can be obtained by the next recurrence relations*

$$\begin{aligned}
B_{ii} &= H_{ii}^{-1}\\
B_{ij} &= -H_{ii}^{-1}(H_{i,i+1}B_{i+1,j}+H_{i,i+2}B_{i+2,j}+\cdots+H_{ij}B_{jj}),\quad i<j.
\end{aligned}$$

Proof. Matrices H and B can be decomposed in an infinite number of finite blocks in the form

$$H=\begin{pmatrix}H_{11}&H_{12}&H_{13}&H_{14}&\cdots\\&H_{22}&H_{23}&H_{24}&\cdots\\&&H_{33}&H_{34}&\cdots\\&&&H_{44}&\cdots\\&&&&\ddots\end{pmatrix},\qquad B=\begin{pmatrix}B_{11}&B_{12}&B_{13}&B_{14}&\cdots\\&B_{22}&B_{23}&B_{24}&\cdots\\&&B_{33}&B_{34}&\cdots\\&&&B_{44}&\cdots\\&&&&\ddots\end{pmatrix}.$$

If we multiply the block-row i-th of H by the block-column i-th of B, or vice versa, we have $H_{ii}B_{ii}=B_{ii}H_{ii}=I$. Then, $B_{ii}=H_{ii}^{-1}$. If we multiply the i-th block-row of H by the j-th

 ISBN: 978-84-617-8694-7

block-column of B, with $i < j$, we obtain

$$H_{ii}B_{ij} + H_{i,i+1}B_{i+1,j} + \cdots + H_{i,j}B_{jj} = 0,$$

then, we have

$$B_{ij} = -H_{ii}^{-1}(H_{i,i+1}B_{i+1,j} + H_{i,i+2}B_{i+2,j} + \cdots + H_{ij}B_{jj}).$$

If we multiply the i-th block-row of H by the j-th block-column of B, with $i > j$, we obtain obviously 0. In a similar way if we multiply block-rows of B by block-columns of H. Each block-column, B_{ij}, is evaluated from the blocks placed under it. □

In the case that matrix H has not two nonzero consecutive entries in subdiagonal, that is, $d_i \cdot d_{i+1} = 0, \forall i$, the inverse matrix is also an upper Hessenberg matrix. We have a necessary and sufficient condition for the inverse of an invertible upper Hessenberg let be also an upper Hessenberg matrix. In a similar way we have the condition for an infinite invertible tridiagonal matrix let be also a tridiagonal matrix. There are the next theorem and the next corollary.

Theorem 2. *A necessary and sufficient condition for that the infinite invertible upper Hessenberg matrix $H = (h_{ij})$ has a classical inverse matrix that be also an upper Hessenberg matrix, is that verify $h_{i+1,i} \cdot h_{i+2,i+1} = 0$ for all $i = 1, 2, ...$ In this case, the classic inverse matrix is unique.*

Proof. Necessary condition: If an infinite matrix H has nonzero entries on its subdiagonal, it is an unreduced matrix, and then, if it is invertible, its classical inverse matrix $B = (b_{ij})$ has the form $B = UV + T$, as we have shown in Lemma 2. Hence, its classical inverse matrix is a full matrix.

If an infinite matrix H has a zero entry in $[n+1, n]$, we consider matrix H divided in blocks as

$$H = \left(\begin{array}{c|c} H_{11} & H_{12} \\ \hline 0 & H_{22} \end{array}\right),$$

where H_{11} is an $n \times n$ finite invertible matrix and H_{22} is an infinite invertible matrix. Entries of H_{11}^{-1} are given by expression (7) of [11], that is

$$(H^{-1})_{ij} = \frac{(-1)^{i+j}\left(\prod_{k=2}^{i} h_{k,k-1}\right)\left(\det H_{j-1} \det H_{n-i}^{(i)} - \det H_{j-i-1}^{(i)} \det H_{11}\right)}{\left(\prod_{k=2}^{j} h_{k,k-1}\right) \det H_{11}},$$

and in the case $i \geq j$, by expression (8) of [11], we have

$$(H^{-1})_{ij} = (-1)^{i+j} \frac{\left(\prod_{k=0}^{i-j-1} h_{i-k,i-k-1}\right) \det H_{j-1} \det H_{n-i}^{(i)}}{\det H_{11}},$$

 ISBN: 978-84-617-8694-7

where determinants of H_{j-1}, $H_{n-i}^{(i)}$ and H_{11} are nonzero because matrix H is invertible. Then, as H_{11}^{-1} is an upper Hessenberg matrix, for $i > j+1$, we have $(H_{11}^{-1})_{ij} = 0$, that is $\prod_{k=0}^{i-j-1} h_{i-k,i-k-1} = 0$. In particular, for $i = j+2$ we have $h_{i,i-1}h_{i-1,i-2} = 0$, $\forall i = 1, 2, ..., n$.

We can repeat the argument if matrix H_{22} plays the rol of matrix H.

Sufficient condition: We need to prove that entries $[i, j]$ in the inverse matrix H_{11}^{-1}, with $i > j+1$, are zero. If infinite matrix H has a zero entry in $[n+1, n]$, we consider the previous division in blocks for H, and the entries of H_{11}^{-1} are given by expression (8) of [11], and then, finite matrix H_{11} has the entry $[i, j]$, with $i > j+1$, given by previous expression and $(H_{11}^{-1})_{ij} = 0$ because one entry $h_{i-k,i-k-1}$ is zero. This is valid for all entries below the subdiagonal of H^{-1}.

Unicity follows because all the blocks are of finite order. □

Theorem 2 can be applied, in a similar way, to infinite invertible lower Hessenberg matrices.

Corollary 1. *A necessary and sufficient condition for the infinite invertible tridiagonal matrix $T = \{a_i, b_i, c_i\}$ has a classical inverse matrix that be also a tridiagonal matrix, is that verify $a_i \cdot a_{i+1} = 0$ and $c_i \cdot c_{i+1} = 0$ for all $i = 1, 2, ...$ This classic inverse matrix is unique.*

Proof. Tridiagonal matrix T is upper and lower Hessenberg matrix, then with condition in the establishment the inverse matrix T^{-1}, by Theorem 2, is both upper and lower Hessenberg matrix and thus T^{-1} is also tridiagonal. □

Example 2. *Matrix H_1 is an infinite reduced upper Hessenberg matrix and it is invertible. Matrix H_2 is an infinite reduced invertible tridiagonal matrix*

$$H_1 = \left(\begin{array}{ccc|ccc|c} 0 & 0 & 1 & & & & \\ 1 & 0 & 0 & & & & \\ 0 & 1 & 0 & & & & \\ \hline & & & 0 & 0 & 1 & \\ & & & 1 & 0 & 0 & \\ & & & 0 & 1 & 0 & \\ \hline & & & & & & \ddots \end{array}\right), \qquad H_2 = \left(\begin{array}{cc|cc|cc|c} 0 & 1 & & & & & \\ 1 & 0 & & & & & \\ \hline & & 0 & 1 & & & \\ & & 1 & 0 & & & \\ \hline & & & & 0 & 1 & \\ & & & & 1 & 0 & \\ \hline & & & & & & \ddots \end{array}\right),$$

an inverse of H_2 is itself.

 ISBN: 978-84-617-8694-7

Example 3. *Tridiagonal matrix H_3 does not verify the conditions of Corollary 1, it is also a Hessenberg matrix with conditions of Theorem 2:*

$$H_3 = \left(\begin{array}{cc|ccc} 0 & 1 & & & \\ 1 & 0 & 1 & & \\ \hline & & 0 & 1 & \\ & & 1 & 0 & 1 \\ \hline & & & & 0 \quad 1 \\ & & & & 1 \quad 0 \\ \hline & & & & & \ddots \end{array}\right).$$

This matrix is invertible because as lower Hessenberg has nonzero entries in superdiagonal. That is, an unreduced Hessenberg matrix. Its unique classical inverse matrix is

$$B_3 = \begin{pmatrix} 0 & 1 & & & & & & \\ 1 & 0 & 1 & & & & & \\ & & 0 & 1 & & & & \\ & & 1 & 0 & 1 & & & \\ & & & & 0 & 1 & & \\ & & & & 1 & 0 & 1 & \\ & & & & & & 0 & \ddots \\ & & & & & & \ddots & \ddots \end{pmatrix}^{-1} = \begin{pmatrix} 0 & 1 & 0 & -1 & 0 & 1 & 0 & \cdots \\ 1 & 0 & 0 & 0 & 0 & 0 & 0 & \cdots \\ & 0 & 0 & 1 & 0 & -1 & 0 & \cdots \\ & & 1 & 0 & 0 & 0 & 0 & \cdots \\ & & & 0 & 0 & 1 & 0 & \cdots \\ & & & & 1 & 0 & 0 & \cdots \\ & & & & & 0 & 0 & \ddots \\ & & & & & & \ddots & \ddots \end{pmatrix}.$$

Example 4. *Matrix H_4 is a tridiagonal matrix and it verifies the conditions of Corollary 1. Then, its unique classical inverse matrix is B_4 :*

$$H_4^{-1} = \left(\begin{array}{cc|cc|cc|c} 1 & 0 & & & & & \\ \frac{1}{3} & 1 & & & & & \\ \hline & 0 & 1 & 0 & & & \\ & & \frac{1}{3} & 1 & & & \\ \hline & & & 0 & 1 & 0 & \\ & & & & \frac{1}{3} & 1 & \\ \hline & & & & & & \ddots \end{array}\right)^{-1} = B_4 = \left(\begin{array}{cc|cc|cc|c} 1 & 0 & & & & & \\ \frac{-1}{3} & 1 & & & & & \\ \hline & & 1 & 0 & & & \\ & & \frac{-1}{3} & 1 & & & \\ \hline & & & & 1 & 0 & \\ & & & & \frac{-1}{3} & 1 & \\ \hline & & & & & & \ddots \end{array}\right).$$

 ISBN: 978-84-617-8694-7

Example 5. *Matrix H_5 is an upper Hessenberg matrix and it verifies the conditions of Theorem 2. The unique classical inverse matrix is B_5 :*

$$H_5^{-1}=\left(\begin{array}{cc|cc|cc|cc|c} 1 & & 1 & 0 & 1 & 0 & 1 & 0 & \cdots \\ 1 & 1 & 0 & 1 & 0 & 1 & 0 & 1 & \cdots \\ \hline & 0 & 1 & & 1 & 0 & 1 & 0 & \cdots \\ & & 1 & 1 & 0 & 1 & 0 & 1 & \cdots \\ \hline & & & 0 & 1 & & 1 & 0 & \cdots \\ & & & & 1 & 1 & 0 & 1 & \cdots \\ \hline & & & & & 0 & 1 & & \cdots \\ & & & & & & 1 & 1 & \cdots \\ \hline & & & & & & & & \ddots \end{array}\right)^{-1} = B_5 = \left(\begin{array}{cc|cc|cc|cc|c} 1 & & 1 & 0 & 1 & 0 & 1 & 0 & \cdots \\ -1 & 1 & -2 & 1 & -4 & 1 & -8 & 1 & \cdots \\ \hline & & 1 & & 1 & 0 & 1 & 0 & \cdots \\ & & -1 & 1 & -2 & 1 & -4 & 1 & \cdots \\ \hline & & & & 1 & & 1 & 0 & \cdots \\ & & & & -1 & 1 & -2 & 1 & \cdots \\ \hline & & & & & & 1 & & \cdots \\ & & & & & & -1 & 1 & \cdots \\ \hline & & & & & & & & \ddots \end{array}\right).$$

Example 6. *Matrix H_6 is a Hessenberg matrix with conditions of Theorem 2. The unique classical inverse matrix is*

$$H_6^{-1}=\left(\begin{array}{cc|cc|cc|cc|c} 1 & & \frac{1}{4} & 0 & \frac{1}{16} & 0 & \frac{1}{64} & 0 & \cdots \\ a & 1 & 0 & \frac{1}{4} & 0 & \frac{1}{16} & 0 & \frac{1}{64} & \cdots \\ \hline & 0 & 1 & & \frac{1}{4} & 0 & \frac{1}{16} & 0 & \cdots \\ & & a & 1 & 0 & \frac{1}{4} & 0 & \frac{1}{16} & \cdots \\ \hline & & & 0 & 1 & & \frac{1}{4} & 0 & \cdots \\ & & & & a & 1 & 0 & \frac{1}{4} & \cdots \\ \hline & & & & & 0 & 1 & & \cdots \\ & & & & & & a & 1 & \cdots \\ \hline & & & & & & & & \ddots \end{array}\right)^{-1} = \left(\begin{array}{cc|cc|cc|cc|c} 1 & & \frac{-1}{4} & 0 & & & & & \\ -a & 1 & \frac{a}{2} & \frac{-1}{4} & \frac{-a}{16} & & & & \\ \hline & 0 & 1 & & \frac{-1}{4} & 0 & & & \\ & & -a & 1 & \frac{a}{2} & \frac{-1}{4} & \frac{-a}{16} & & \\ \hline & & & 0 & 1 & & \frac{-1}{4} & 0 & \\ & & & & -a & 1 & \frac{a}{2} & \frac{-1}{4} & \ddots \\ \hline & & & & & 0 & 1 & & \ddots \\ & & & & & & -a & 1 & \ddots \\ \hline & & & & & & & \ddots & \ddots \end{array}\right).$$

3 Reduced Hessenberg matrices related with bounded linear operators

In some cases, Hessenberg matrices can be regarded as bounded linear operators on ℓ^2. We recall here some basic features of the matrix representation of invertible linear operators. A bounded operator T between Hilbert spaces, for example from ℓ^2 to itself, is *invertible* if there exists an operator T^{-1}, obviously bounded, such that $T^{-1}Tx = x$ and $TT^{-1}y = y$ for every $x, y \in \ell^2$. The operator T^{-1} is called the inverse operator of T, and it is unique. A useful method for inverting bounded linear operators is the (iterative) power series method given by next lemma; see e.g. Theorem 8.2 from [5].

 ISBN: 978-84-617-8694-7

Lemma 3. *Let H be a matrix representation of a bounded operator on ℓ^2 that satisfies $||A|| < 1$, where $A = I - H$. Then H is invertible, and its inverse H^{-1},*

$$H^{-1} = \sum_{j=0}^{\infty} A^j = I + A + A^2 + A^3 + \cdots ,$$

is a matrix representation of its inverse operator defined on ℓ^2.

Example 7. *The infinite Hessenberg matrix H_6 from Example 6 satisfies $H_6 = I - A$, where A is the matrix*

$$A = \left(\begin{array}{cc|cc|cc|cc|c} 0 & & \frac{-1}{4} & 0 & \frac{-1}{16} & 0 & \frac{-1}{64} & 0 & \cdots \\ -a & 0 & 0 & \frac{-1}{4} & 0 & \frac{-1}{16} & 0 & \frac{-1}{64} & \cdots \\ \hline & 0 & 0 & & \frac{-1}{4} & 0 & \frac{-1}{16} & 0 & \cdots \\ & & -a & 0 & 0 & \frac{-1}{4} & 0 & \frac{-1}{16} & \cdots \\ \hline & & & 0 & 0 & & \frac{-1}{4} & 0 & \cdots \\ & & & & -a & 0 & 0 & \frac{-1}{4} & \cdots \\ \hline & & & & & 0 & 0 & & \cdots \\ & & & & & & -a & 0 & \cdots \\ \hline & & & & & & & \vdots & \ddots \end{array}\right).$$

If $|a| < \frac{2}{3}$, then is $||A|| < 1$. Hence H_6, as a matrix representation of a bounded linear operator in ℓ^2, is invertible. The matrix B_6 from Example 6 is a matrix representation of its inverse operator.

The infinite Hessenberg matrix H_5 from Example 5 satisfies also $H_5 = I - A$, where A is the matrix

$$A = \left(\begin{array}{cc|cc|cc|cc|c} 0 & 0 & -1 & 0 & -1 & 0 & -1 & 0 & \cdots \\ -1 & 0 & 0 & -1 & 0 & -1 & 0 & -1 & \cdots \\ \hline & 0 & 0 & 0 & -1 & 0 & -1 & 0 & \cdots \\ & & -1 & 0 & 0 & -1 & 0 & -1 & \cdots \\ \hline & & & 0 & 0 & 0 & -1 & 0 & \cdots \\ & & & & -1 & 0 & 0 & -1 & \cdots \\ \hline & & & & & 0 & 0 & 0 & \cdots \\ & & & & & & -1 & 0 & \cdots \\ \hline & & & & & & & & \ddots \end{array}\right).$$

In this case, H_5 is not a bounded linear operator in ℓ^2. The matrix B_5 from Example 5 is the unique classical inverse matrix of H_5, but is not the representation of a bounded operator.

 ISBN: 978-84-617-8694-7

The infinite tridiagonal matrix H_4 from Example 4 satisfies also $H_4 = I - A$, where A is the matrix

$$A = \left(\begin{array}{cc|cc|cc|c} 0 & 0 & & & & & \\ \frac{-1}{3} & 0 & & & & & \\ \hline & & 0 & 0 & & & \\ & & \frac{-1}{3} & 0 & & & \\ \hline & & & & 0 & 0 & \\ & & & & \frac{-1}{3} & 0 & \\ \hline & & & & & & \ddots \end{array}\right),$$

with norm $||A|| < 1$. Hence H_4, as a matrix representation of a bounded linear operator in ℓ^2, is invertible. The matrix B_4 from Example 4 is a matrix representation of its inverse operator.

Recall that a matrix H can have infinitely many classical inverses. Nevertheless, if H is a matrix representation of an invertible bounded operator, it has a unique inverse. Such an inverse is also a matrix representation of its inverse bounded linear operator, as those given in Example 7.

Some reduced tridiagonal matrices with specific invertible blocks can be inverted by blocks, as we shown in next example.

Example 8. *If we take $0 < a, b < 1$, matrix T_1 verifies $||I - T_1|| < 1$ and T_1 is an invertible bounded operator with*

$$T_1^{-1} = \left(\begin{array}{cc|cc|c} 1 & b & & & \\ a & 1 & & & \\ \hline & & 1 & b & \\ & & a & 1 & \ddots \\ & & & \ddots & \ddots \end{array}\right)^{-1} = \left(\begin{array}{cc|cc|c} \frac{1}{1-ab} & \frac{-b}{1-ab} & & & \\ \frac{-a}{1-ab} & \frac{1}{1-ab} & & & \\ \hline & & \frac{1}{1-ab} & \frac{-b}{1-ab} & \\ & & \frac{-a}{1-ab} & \frac{1}{1-ab} & \ddots \\ & & & \ddots & \ddots \end{array}\right).$$

The same happens with matrix T_2 if $0 < a, b < \frac{1}{2}\cdot$ The inverse operator is

$$T_2^{-1} = \left(\begin{array}{cc|cc|cc} 1 & 0 & & & & \\ a & 1 & b & & & \\ \hline & & 1 & 0 & & \\ & & a & 1 & b & \\ \hline & & & & 1 & \ddots \\ & & & & \ddots & \ddots \end{array}\right)^{-1} = \left(\begin{array}{cc|cc|cc} 1 & 0 & & & & \\ -a & 1 & -b & & & \\ \hline & & 1 & 0 & & \\ & & -a & 1 & -b & \\ \hline & & & & 1 & \ddots \\ & & & & \ddots & \ddots \end{array}\right).$$

Abstract

In this work, we compare continuous and discrete models for the propagation of bovine Babesiosis disease among bovine and ticks populations. From our continuous-time model based on ordinary differential equations, we derive its discretization both ways: by direct formulation of the model and by using the forward Euler scheme. We show that the reproductive parameter $\mathcal{R}_0$ plays an important role in the existence and stability of the equilibrium points for the different versions. Finally, we conclude from some numerical simulations that the dynamics do not change when varying the value of the step size till a threshold value corresponding to the Euler discretization.

Key words: Bovine Babesiosis, continuous-time model, discrete-time model, forward Euler Scheme, Local and global stability.

1 Extended abstract

The bovine Babesiosis is a parasitic zoonotic disease transmitted by ticks and is produced by protozoan as *Babesia bovis* and *Babesia bigemina*. The bovine Babesiosis cause great economic losses to cattle farmers in tropical and subtropical climates around the world.

The first mathematical continuous deterministic model known for the spread of bovine Babesiosis was proposed by Aranda et al. [1] and consists of five ordinary differential equations. In 2014, Friedman and Yakubu [5] included the factor of dispersion for the bovine population and ticks converting the model in [1] into a system of partial differential equations and introducing a parameter $\mathcal{P}$, a *proliferation index*, which plays the same role as the *basic reproduction number*, $\mathcal{R}_0$, in our work [1]. Carvalho et al. [4] incorporated the memory effect in the model. They changed normal derivative by the Caputo derivative. Also in this sense, Zafar et al. [10] study a fractional-order scheme version of our model. Other works take into account factors such as the juvenile stage of the cattle population [9] or the effects of seasonal changes [3]. On the other hand, in [8], the authors use a computational multistage algorithm modified for approximating solutions of the model in [1] in a sequence of (time) intervals.

 ISBN: 978-84-617-8694-7

For our purposes, we assume an homogeneous-mixing for the disease dynamics. That is, all the populations have same rates of disease-causing contacts. The bovine population $N_B(t)$ is split into three subpopulations, namely, susceptible $\bar{S}_B(t)$; infected $\bar{I}_B(t)$; and controlled $\bar{C}_B(t)$, i.e., treated against Babesiosis. Ticks population, $N_T(t)$, is only divided into two subpopulations susceptible $\bar{S}_T(t)$ and infected $\bar{I}_T(t)$. The susceptible cattle may become infected due to ticks bites infected by the parasite at a rate β_B and susceptible ticks may become infected after a blood meal on infected bovine at a rate β_T. Parameters λ_B and α_B are the fractions of infected bovines which are controlled and of controlled bovines which return to be susceptible to parasite, respectively. We consider, in the tick population, vertical transmission of bovine Babesiosis with probability $1-p$. The birth and death rates are considered equal in each population, being denoted by μ_B for the bovine population and μ_T for the tick population.

Under the above assumptions, we obtained the continuous model described by the following system of first order equations [1]:

$$\begin{cases} \bar{S}_B(t) = \mu_B(\bar{S}_B(t)+\bar{C}_B(t)) + \alpha_B\bar{C}_B(t) - \mu_B\bar{S}_B(t) - \beta_B\bar{S}_B(t)\dfrac{\bar{I}_T(t)}{N_T(t)}, \\ \bar{I}_B(t) = \mu_B\bar{I}_B + \beta_B\bar{S}_B(t)\dfrac{\bar{I}_T(t)}{N_T(t)} - \mu_B\bar{I}_B - \lambda_B\bar{I}_B(t), \\ \bar{C}_B(t) = \lambda_B\bar{I}_B(t) - (\mu_B+\alpha_B)\,\bar{C}_B(t), \\ \bar{S}_T(t) = \mu_T(\bar{S}_T + p\bar{I}_T) - \beta_T\bar{S}_T(t)\dfrac{\bar{I}_B(t)}{N_B(t)} - \mu_T\bar{S}_T(t), \\ \bar{I}_T(t) = \beta_T\bar{S}_T(t)\dfrac{\bar{I}_B(t)}{N_B(t)} + (1-p)\mu_T\bar{I}_T(t) - \mu_T\bar{I}_T(t), \end{cases} \tag{1}$$

For simplicity, we considered the bovine and tick populations as constants, i.e., $N_B'(t) = 0$ and $N_T'(t) = 0$. Also, we introduced the following proportions

$$S_B(t) = \frac{\bar{S}_B(t)}{N_B(t)},\ I_B(t) = \frac{\bar{I}_B(t)}{N_B(t)},\ C_B(t) = \frac{\bar{C}_B(t)}{N_B(t)},\ S_T(t) = \frac{\bar{S}_T(t)}{N_T(t)},\ I_T(t) = \frac{\bar{I}_T(t)}{N_T(t)},$$

and equalities $C_B(t) = 1 - S_B(t) - I_B(t)$ and $S_T(t) = 1 - I_T(t)$. The model (1) is reduced to a normalized system with three differential equations of first order:

$$\begin{cases} S_B'(t) = (\mu_B+\alpha_B)\,(1 - S_B(t) - I_B(t)) - \beta_B I_T(t) S_B(t) \\ I_B'(t) = \beta_B S_B(t) I_T(t) - \lambda_B I_B(t), \\ I_T'(t) = \beta_T\,(1 - I_T(t))\,I_B(t) - \mu_T p I_T(t). \end{cases} \tag{2}$$

Here, all the parameters involved are considered non-negative.

For our direct discrete-time epidemic model [2], we assume that the population in the $(t+1)-th$ generation is a function of the $t-th$ generation with $t \in \mathbb{N}$. With similar procedures as above, we directly obtain the following system of difference equations:

$$\begin{cases} S_B(t+1) = S_B(t) + (\mu_B+\alpha_B)\,(1 - S_B(t) - I_B(t)) - \beta_B I_T(t) S_B(t) \\ I_B(t+1) = I_B(t) + \beta_B S_B(t) I_T(t) - \lambda_B I_B(t), \\ I_T(t+1) = I_T(t) + \beta_T\,(1 - I_T(t))\,I_B(t) - \mu_T p I_T(t). \end{cases} \tag{3}$$

On the other hand, using discretization schemes, we obtain a more complex discrete model. In particular, we use the forward Euler scheme (see [6] and [7]).

 ISBN: 978-84-617-8694-7

Specifically, we choose a time step size $h > 0$, for any $t \geq 0$. Taking into account the above assumptions, we get the system:

$$\begin{cases} S_B(t+1) = [1 - h(\mu_B + \alpha_B + \beta_B I_T(t))] S_B(t) + h(\mu_B + \alpha_B)(1 - I_B(t)) \\ I_B(t+1) = [1 - h\lambda_B] I_B(t) + h\beta_B S_B(t) I_T(t), \\ I_T(t+1) = [1 - h(\mu_T p + \beta_T I_B(t))] I_T(t) + h\beta_T I_B(t), \end{cases} \tag{4}$$

for all initial conditions $S_B(t_0) > 0$, $I_B(t_0) > 0$ and $I_T(t_0) > 0$ satisfying $S_B(t_0) + I_B(t_0) = 1$ and $I_T(t_0) > 0$ with $t_0 \in \mathbb{N}$.

We assume as the state space of systems (3) and (4) the set

$$\Omega = \left\{(S_B, I_B, I_t) \in \mathbb{R}^3_+ : 0 \leq S_B + I_B \leq 1, 0 \leq I_T \leq 1\right\}$$

which is a positive invariant set.

If the step size $h = 1$ in the model (4), we obtain the model (3) above. The model (3) is epidemiologically meaningful if, and only if, the parameters involved in modeling verifies the following constraints

$$1 - (\mu_B + \alpha_B) \geq 0, \quad 1 - \beta_B \geq 0, \quad 1 - \lambda_B \geq 0, \quad 1 - \beta_T \geq 0, \quad 1 - \mu_T p \geq 0.$$

These constraints are fundamental in order to prove results similar to the continuous system (2).

The mathematical results related to model (4) are similar to models (2) and (3) for $0 < h \leq 1$, i.e, the equilibrium points existence and stability depend only on the threshold parameter:

$$\mathcal{R}_0 = \frac{\beta_B \beta_T}{\lambda_B \mu_T p}.$$

When $\mathcal{R}_0 < 1$, the system has also the two equilibria, disease-free equilibrium asymptotically stable in Ω and endemic equilibrium unstable, being the last one in the outside of Ω. If the parameter value $\mathcal{R}_0 = 1$ the system undergoes a transcritical bifurcation.

Nevertheless, when $h > 1$, exists a theshold value, h^*, such that the disease-free equilibrium is asymptotically stable into Ω, for $h < h^*$, where

$$h^* = \min\left\{\frac{1}{\beta_B}, \frac{1}{\beta_T}, \frac{1}{\lambda_B}, \frac{1}{\mu_B + \alpha_B}, \frac{1}{\mu_T p}\right\}.$$

If $h > h^*$, the desease-free equilibrium is unstable.

Besides, we are able to confirm the absence of contradictions between the different versions. These results have been validated by numerical simulations.

Abstract

The generalised finite differences method allows the use of irregular clouds of nodes. The optimal values of the key parameters of the method vary depending on how the nodes in the cloud are distributed and this may be specially complicated in 3D. Therefore, we establish two criteria to allow the automation of the selection process of the key parameters. These criteria depends on two discrete functions, one of them penalises distances and the other penalises imbalances.

We propose an improved and more versatile h-adaptive method that allows adding, moving and removing nodes. In order to decide on which nodes to act we use an indicator of the error a posteriori. This h-adaptive method gives more accuracy results than those presented for the generalised finite differences method so far and, in addition, using fewer nodes.

Key words: Meshless method, Generalised finite differences, Adaptive method
MSC 2000: 65M06

1 Introduction

The generalised finite differences method, from here onwards GFDM, is a meshless method that allows, unlike the classical finite differences method, to solve partial differential equations over domains where a regular grid is not possible.

An overview of advances in h-adaptive methods with the GFDM so far may be as follows. In [1] an error indicator is defined and compared to the error proposed by Orkisz in [2] with similar results but lower computational cost. Moreover, in [3], a quality index for the error indicator is used in order to analyse its efficiency. Also in [1] two parameters associated with the adaptive process arise, a limit for the distance to which a new node can be placed (dpa) and a threshold of the error to be reached. Both parameters should be reduced little by little in several steps. In [4] the GFDM and the EFG method are compared, obtaining better results in the first one. In [4] it is also showed a case where a strategic irregularity provides results almost as accuracy as those provided by a finer discretisation. The GFDM and classical finite differences are compared in [5], obtained better results in the first one. Moreover, it is proposed an adaptive method based on adding a node in the barycentre of the triangles with higher area formed in each star. In [6] an index of irregularity of a cloud of nodes is defined. The quadtree method is applied in cloud of nodes with sharp variations of gradient in [7].

In this paper, we make the following contributions. Firstly, we define two penalty functions based on distances and imbalances in each star and, in this way, we establish two criteria to choose the number of nodes, the criterion of selection and the potential weighting function. This is specially important in 3D. Secondly, all adaptive methods analysed in previous works have been put together in an improved method with new functionalities such as the ability of moving and removing nodes. Our aim is to reach error reductions as low as possible with the fewest number of nodes and for that reason the quadtree method is not included in this paper.

2 Theoretical background

Given a domain $D \subset \mathbb{R}^n$, $n = 2, 3$, the aim is to solve a problem defined by the second order linear partial differential equation

$$\mathcal{L}_2\big(U(\mathbf{x})\big) = f(\mathbf{x}) \qquad \forall \mathbf{x} \in \Omega = int(D) \tag{1}$$

with boundary condition

$$\mathcal{L}_1\big(U(\mathbf{x})\big) = g(\mathbf{x}) \qquad \forall \mathbf{x} \in \Gamma = fr(D) \tag{2}$$

where $\mathbf{x} \in D$, U is the unknown function and f and g are continuous functions.

 ISBN: 978-84-617-8694-7

In order to solve the problem, a discretisation M of the domain is considered and for each star in the discretisation, it is defined the function given by the sum of the weighted quadratics errors in Taylor series for terms over third order

$$B(\mathbf{D}_u) = \sum_{i=1}^{N} \left(u_0 - u_i + \boldsymbol{\varepsilon}_i^T \mathbf{D}_u \right)^2 w_i^2 \tag{3}$$

where N is the number of nodes of the star, $w_i = w(\mathbf{x}_0, \mathbf{x}_i)$ is the weighting function and $u_0 = u(\mathbf{x}_0)$ and $u_i = u(\mathbf{x}_i)$ are the approximations of $U_0 = U(\mathbf{x}_0)$ and $U_i = U(\mathbf{x}_i)$, respectively. In both 2D and 3D, the vectors $\mathbf{D}_u$ and $\boldsymbol{\varepsilon}_i$ are

$$\mathbf{D}_u = \begin{cases} \left(\dfrac{\partial u_0}{\partial x} \quad \dfrac{\partial u_0}{\partial y} \quad \dfrac{\partial^2 u_0}{\partial x^2} \quad \dfrac{\partial^2 u_0}{\partial x \partial y} \quad \dfrac{\partial^2 u_0}{\partial y^2} \right)^T \\ \left(\dfrac{\partial u_0}{\partial x} \quad \dfrac{\partial u_0}{\partial y} \quad \dfrac{\partial u_0}{\partial z} \quad \dfrac{\partial^2 u_0}{\partial x^2} \quad \dfrac{\partial^2 u_0}{\partial y^2} \quad \dfrac{\partial^2 u_0}{\partial z^2} \quad \dfrac{\partial^2 u_0}{\partial x \partial y} \quad \dfrac{\partial^2 u_0}{\partial x \partial z} \quad \dfrac{\partial^2 u_0}{\partial y \partial z} \right)^T \end{cases} \tag{4}$$

$$\boldsymbol{\varepsilon}_i = \begin{cases} \left(h_i \quad k_i \quad \dfrac{h_i^2}{2} \quad h_i k_i \quad \dfrac{k_i^2}{2} \right)^T \\ \left(h_i \quad k_i \quad l_i \quad \dfrac{h_i^2}{2} \quad \dfrac{k_i^2}{2} \quad \dfrac{l_i^2}{2} \quad h_i k_i \quad h_i l_i \quad k_i l_i \right)^T \end{cases} \tag{5}$$

In order to minimise the error, this function is minimised and the following system is obtained

$$A\mathbf{D}_u = \mathbf{b} \tag{6}$$

where

$$A = \sum_{i=1}^{N} w_i^2 \boldsymbol{\varepsilon}_i \boldsymbol{\varepsilon}_i^T \tag{7}$$

$$\mathbf{b} = \sum_{i=1}^{N} w_i^2 (u_i - u_0) \boldsymbol{\varepsilon}_i \tag{8}$$

Solving for $\mathbf{D}_u$, the approximated values of the partial derivatives are obtained and, substituting these values in the original equation (1), the *equation of the star* is attained

$$-\lambda_0 u_0 + \sum_{i=1}^{N} \lambda_i u_i = f \tag{9}$$

The numerical values in each inner node are obtained solving the linear system of equations formed by all equations of the star. For more details about this, see [8] and [9].

 ISBN: 978-84-617-8694-7

2.1 Criteria for selecting the key parameters of the stars

Definition 1 (Radius of the star) *The radius of a star is defined as the average distance between the central node and the rest of the nodes of the star and is denoted by* $\overline{sr}$.

Definition 2 (Distance penalty function of a star) *The distance penalty function of a star,* $f_d : \Omega \longrightarrow [0,1]$*, is defined as the numbers of nodes outside the interval* $[\overline{sr} - 2\sigma_{sr}, \overline{sr} + 2\sigma_{sr}]$ *divided by the number of nodes of the star, being* σ_{sr} *the standard deviation of the distances between the central node and the rest of the nodes.*

Given a star with N nodes, the number of nodes by octant (quadrant) is the integer part of $N/8$ ($N/4$) and it is denoted by NO.

Definition 3 (Imbalance penalty function of a star) *The imbalance penalty function of a star,* $f_b : \Omega \longrightarrow [0,1]$*, is defined as the sum of the number of missing or extra nodes by octant (quadrant) divided by the maximum possible penalty in the star.*

The maximum possible penalty is $N + 6NO$ in 3D and $N + 2NO$ in 2D.

The index of irregularity of a cloud of nodes (IIC) defined in [6] gives an insight of how irregular the cloud is but it does not provide information about the choice of the number of nodes, the criterion of selection and the exponent of the potential weighting function. Although we know that the optimal parameters are 18 nodes with the distance criterion and 24 nodes with the octant criterion and, with regard to the weighting function, the potential function give better results than exponential ones, we want to know which the best choice is in each case and, for this purpose, we apply the following empirical criteria, as it will be seen in the examples in section 3.2.

If a cloud of nodes has some star whose balance penalty function is greater than 0.5, then 24-stars formed by the octant criterion are chosen. Otherwise, 18-stars formed by the distance criterion are chosen.

If a cloud of nodes has more than 25% of its stars with positive values of the distance penalty function, then low exponents in the potential weighting functions are chosen. Otherwise, higher exponents may be chosen.

Although the penalty functions will be used in 2D and 3D, these criteria are established only for 3D cases because that is where they really are needed.

2.2 H-adaptive method

Two algorithms are distinguished in the h-adaptive method, one that allows the addition of nodes and another that allows movement and elimination. In both algorithms, a node will be processed if the estimation of the error in that node is above a given value. The errors are calculated with the indicator obtained in [1].

 ISBN: 978-84-617-8694-7

Addition algorithm. In 2D case, we use the algorithm defined in [5] that adds in each selected node a new node in the barycentre of the triangles with higher area. In 3D case and for each star, the algorithm adds nodes halfway between the selected node and the central node. To do this, the algorithm handles two options, the first one selects the farthest node and adds a single node and the second one selects the nodes whose distance is greater than the radius of the star and adds the corresponding nodes. In all cases, a new node is added if the distance with the rest of the nodes is less than $\alpha \cdot dpa$, $\alpha \in (0, 1]$. *dpa* is the minimum distance between whatever two nodes in the cloud.

Movement algorithm. The next algorithm will be implemented jointly with the previous and may be applied in any domain. For each star $E(\mathbf{x}_0) = \{\mathbf{x}_0; \mathbf{x}_1, \mathbf{x}_2, ..., \mathbf{x}_N\}$, we will consider the connections between the central node and the other nodes of the star as vectors whose starting point is the central node. The algorithm modifies the position of the central node of the star. The new position of the central node will be determined by the ending point of the resultant vector obtained by adding the N vectors, each of which will be weighted by the estimation of the error (e_i) on that node, namely, the linear combination

$$\overrightarrow{u_0} = \varphi_E(e_1)\overrightarrow{u_1} + \varphi_E(e_2)\overrightarrow{u_2} + ... + \varphi_E(e_N)\overrightarrow{u_N} \tag{10}$$

where $\overrightarrow{u_0} = \overrightarrow{\mathbf{x}_0\overline{\mathbf{x}}_0}$ with $\overline{\mathbf{x}}_0$ the new position of the central node, $\overrightarrow{u_i} = \overrightarrow{\mathbf{x}_0\mathbf{x}_i}, \forall i = 1, ..., N$ and φ_E the weighting function for the star E defined in terms of the estimation of the error is as follows

$$\varphi_E(e_i) = \frac{\frac{1}{\kappa + e_i}}{S_E} \tag{11}$$

where $\kappa > 0$ is a constant to avoid problems with null values such as in Dirichlet boundary and

$$S_E = \sum_{i=1}^{N} \frac{1}{\kappa + e_i} \tag{12}$$

In order to implement the algorithm, the following constraints are taken into account:

C1. If the distance between the new position of the central node and the old one is greater than $\mu \cdot dmm$, with $0 < \mu < 1$ and dmm the minimum distance between the central node and the other nodes of the star, then the new position of the central node is in the direction of the resultant vector but at distance of $\mu \cdot dmm$.

C2. If the distance from the new position of the central node to any node of the discretisation is less than $\alpha \cdot dpa$ the node is removed.

This movement algorithm helps to reduce the global error because of the reduction of the estimation of the error in the node itself as a consequence of improving the distribution of the nodes and because it produces a node repulsion effect in areas with close nodes and large values of the error, making spaces which can be occupied by new nodes in the adding step. In addition, it may be that, due to specific errors in the initial configuration of the cloud, the initial *dpa* distance is smaller than expected and then it is possible to establish a

 ISBN: 978-84-617-8694-7

distance *dpa* higher than the one obtained automatically in order to remove the nodes with the highest estimation of the error.

It is important to notice that both addition and movement algorithm must be used with stars formed by the octant criterion since the cloud of nodes will become more irregular in each step. For this reason, and whenever the committed error when using stars formed by the distance criterion is less than the committed error when using stars formed by the octant criterion, we show that error using the distance criterion in the examples and verify that the adaptive method reduces it.

In summary, we have three algorithms, one in 2D and two in 3D, to add nodes (addition algorithm), an algorithm to move nodes (movement algorithm) and an adaptive method that brings them together.

3 Numerical results

The error is evaluated using the following global error formula:

$$\text{Global Error } (\%) = \frac{1}{|e_{max}|}\sqrt{\frac{\sum_{i=1}^{NI} e_i^2}{NI}} \times 100 \tag{13}$$

where e_{max} is the maximum value of the error indicator and NI is the number of inner nodes.

In order to compare the addition algorithm and the adaptive method, four partial differential equations are solved in four irregular clouds of nodes. The movement algorithm will be implemented alternately with the addition algorithm. Moreover, in both algorithms, a node will be processed if the estimation of the error in that node is above the average of the estimation of the error in the whole cloud plus twice standard deviation. In all cases the values for the different parameters are $\alpha = 0.5$, $\mu = 2/3$ and $\kappa = max(e_1, \ldots, e_N)$, being e_i, $i = 1, \ldots, N$, the estimation of the error in each node of the star.

In 3D cases it is difficult to visualize the distribution of nodes but, despite this, we show both the initial and final clouds of nodes so that the difference can be appreciated.

3.1 Comparison between the addition algorithm and the adaptive method

Example 1. We consider the following equation over an arbitrary irregular domain contained in $D = [0, 3] \times [0, 2]$

$$\frac{\partial^2 U}{\partial x^2} + \frac{\partial^2 U}{\partial y^2} = 0 \tag{14}$$

with Dirichlet boundary conditions and exact solution

$$U(x, y, z) = \ln(x^2 + y^2) \tag{15}$$

 ISBN: 978-84-617-8694-7

where 8-stars formed with the quadrant criterion and weighting function $w(\mathbf{x}_0, \mathbf{x}_i) = \|\mathbf{x}_i - \mathbf{x}_0\|^{-4}$ have been used in each node.

Eight steps have been taken with the addition algorithm (barycentre method) and eight steps have been taken with the adaptive method. The error value is improved by adaptive method even using less nodes than the addition algorithm, as can be seen in table 1. Fig. 1 shows the initial cloud (55 nodes) and the final cloud (120 nodes) when adaptive method has been applied.

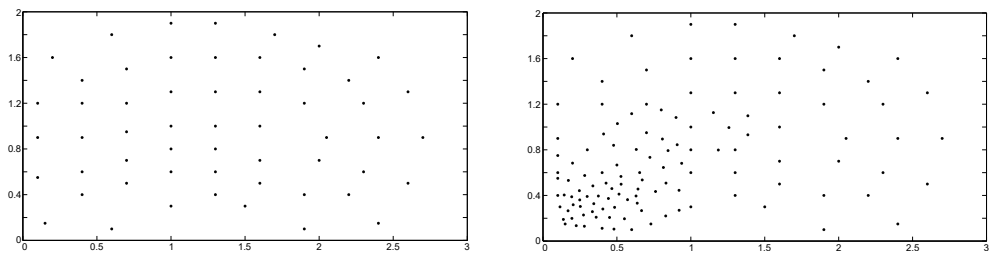

Figure 1: Cloud of nodes, initial (55 nodes) and final (120 nodes), applying the adaptive method in example 1

Table 1: Initial and final errors and number of nodes

Example 1	Initial error (nodes)	Final error (nodes)
Addition algorithm	$6.16 \cdot 10^{-1}\%$ (55)	$3.58 \cdot 10^{-2}\%$ (138)
Adaptive method	$6.16 \cdot 10^{-1}\%$ (55)	$3.29 \cdot 10^{-2}\%$ (120)

Example 2. We consider the following equation over an arbitrary irregular domain contained in $D = [0, 1]^3$

$$\frac{\partial^2 U}{\partial x^2} + \frac{\partial^2 U}{\partial y^2} + \frac{\partial^2 U}{\partial z^2} = \frac{20}{x^2 + y^2 + z^2} \tag{16}$$

with Dirichlet boundary conditions and exact solution

$$U(x, y, z) = 10 \ln(x^2 + y^2 + z^2) \tag{17}$$

where 24-stars formed with the octant criterion and weighting function $w(\mathbf{x}_0, \mathbf{x}_i) = \|\mathbf{x}_i - \mathbf{x}_0\|^{-6}$ have been used in each node.

Three steps have been taken with the second option of the addition algorithm and two steps have been taken with the adaptive method. The estimation of the initial error using

 ISBN: 978-84-617-8694-7

a star with 18 nodes formed by the distance criterion is $7,37 \cdot 10^{-2}\%$ and this value is improved by the adaptive method as can be seen in table 2. Fig. 2 shows the initial cloud (216 nodes) and the final cloud (250 nodes) when the adaptive method has been applied.

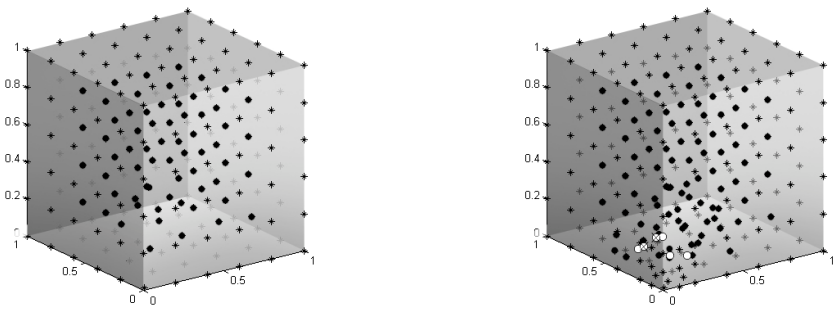

Figure 2: Cloud of nodes, initial (216 nodes) and final (250 nodes), applying the adaptive method in example 2. Legend: $\star$ boundary node, $\triangle$ inner node initial position, $\circ$ inner node final position, $\otimes$ removed node.

Table 2: Initial and final errors and number of nodes

Example 2	Initial error (nodes)	Final error (nodes)
Addition algorithm	$1,30 \cdot 10^{-1}\%$ (216)	$2,76 \cdot 10^{-2}\%$ (263)
Adaptive method	$1,30 \cdot 10^{-1}\%$ (216)	$2,54 \cdot 10^{-2}\%$ (250)

Example 3. We consider the following equation over an arbitrary irregular domain contained in $D = [0,1]^3$

$$\frac{\partial^2 U}{\partial x^2} + \frac{\partial^2 U}{\partial y^2} + \frac{\partial^2 U}{\partial z^2} = 0 \tag{18}$$

with Dirichlet boundary conditions and exact solution

$$U(x,y,z) = e^x \sin y + e^y \sin z + e^z \sin x \tag{19}$$

where 24-stars formed with the octant criterion and weighting function $w(\mathbf{x}_0, \mathbf{x}_i) = \|\mathbf{x}_i - \mathbf{x}_0\|^{-4}$ have been used in each node.

A single step has been taken with both algorithms. Fig. 3 shows the initial cloud of nodes (136 nodes) and the final one (137 nodes) obtained when the adaptive method has been applied. How the error decreases with the first option of the addition algorithm and with the adaptive method can be seen in table 3.

 ISBN: 978-84-617-8694-7

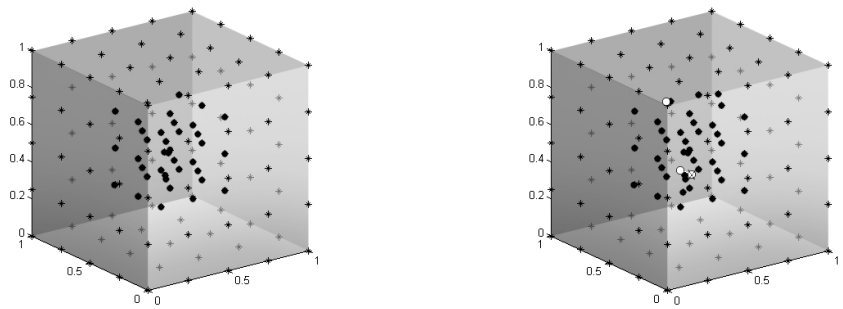

Figure 3: Clouds of nodes, initial (136 nodes) and final (137 nodes), applying the adaptive method in example 3. Legend: $\star$ boundary node, $\triangle$ inner node initial position, $\circ$ inner node final position, $\otimes$ removed node.

Table 3: Initial and final errors and number of nodes

Example 3	Initial error (nodes)	Final error (nodes)
Addition algorithm	$7,47 \cdot 10^{-3}\%$ (136)	$7,11 \cdot 10^{-3}\%$ (138)
Adaptive method	$7,47 \cdot 10^{-3}\%$ (136)	$4,39 \cdot 10^{-3}\%$ (137)

Example 4. We consider the following equation over an arbitrary irregular domain, in particular, the sphere with centre the origin and radius 0.7.

$$\frac{\partial^2 U}{\partial x^2} + \frac{\partial^2 U}{\partial y^2} + 2\frac{\partial^2 U}{\partial z^2} = 0 \tag{20}$$

with Dirichlet boundary conditions and exact solution

$$U(x, y, z) = e^z \sin x \cos y \tag{21}$$

where 24-stars formed with the octant criterion and weighting function $w(\mathbf{x}_0, \mathbf{x}_i) = \|\mathbf{x}_i - \mathbf{x}_0\|^{-4}$ have been used in each node.

Three steps have been taken with the first option of the addition algorithm and two steps have been taken with the adaptive method. Fig. 4 shows the initial cloud of nodes (575 nodes) and the final one (582 nodes) obtained when the adaptive method has been applied. Table 4 shows how the error decreases when the addition algorithm and the adaptive method are applied.

 ISBN: 978-84-617-8694-7

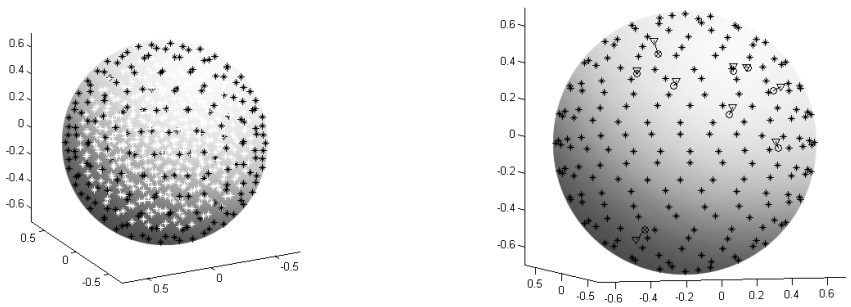

Figure 4: Clouds of nodes, initial (575 nodes) and final (582 nodes), applying the adaptive method in example 4. Legend: ($\star$ boundary node, $\triangle$ inner node initial position, $\circ$ inner node final position, $\otimes$ removed node.)

Table 4: Initial and final errors and number of nodes

Example 4	Initial error (nodes)	Final error (nodes)
Addition algorithm	$2,60 \cdot 10^{-2}\%$ (575)	$2,41 \cdot 10^{-2}\%$ (584)
Adaptive method	$2,60 \cdot 10^{-2}\%$ (575)	$1,94 \cdot 10^{-2}\%$ (582)

3.2 Selection of the key parameters of the stars in 3D

In order to check the most favourable choice of the parameters of the stars (number of nodes, criterion of selection and exponent of the weighting function), we use the 3D examples from the previous section. The best choice for the parameters has the error in bold in Tables 6 and 7 and it is in accordance with the established criteria in this paper as it is showed in Table 5. In Table 6 we vary the number of nodes and the criterion of selection using the optimal exponent, according with the distance penalty criterion, in each case. In Table 7 we vary the exponent of the weighting function using the optimal number of nodes and selection criterion, according with the imbalance penalty criterion, in each case.

Table 5: Criteria for selecting the key parameters of the stars

Penalty	Example 2	Example 3	Example 4
Imbalance	0	7	0
Distance	6	19	174

 ISBN: 978-84-617-8694-7

Table 6: Errors depending on the number of nodes and the criterion of selection (DC = Distance criterion and OC = Octant criterion)

Error	Example 2	Example 3	Example 4
18 and DC	$\mathbf{7.37 \cdot 10^{-2}}$	$4.29 \cdot 10^{-1}$	$\mathbf{2.16 \cdot 10^{-2}}$
24 and OC	$1.30 \cdot 10^{-1}$	$\mathbf{7.47 \cdot 10^{-3}}$	$2.60 \cdot 10^{-2}$

Table 7: Errors depending on the exponent of the weighting function

Error	Example 2	Example 3	Example 4
Exponent 4	$1.20 \cdot 10^{-1}$	$8.34 \cdot 10^{-3}$	$\mathbf{2.16 \cdot 10^{-2}}$
Exponent 6	$\mathbf{7.37 \cdot 10^{-2}}$	$\mathbf{7.47 \cdot 10^{-3}}$	$2.50 \cdot 10^{-2}$

4 Conclusions

Two penalty functions for the stars are defined, one of them for the distances and the other one for the imbalance. As consequence, two criteria are established. These criteria allow an automatic selection of the key parameters of the method in 3D. Several examples have showed the appropriate behaviour of these criteria. The minimum distance *dpa* has been redefined in order to give more insight when the addition algorithm is applied.

An improved h-adaptive method with more functionalities has been introduced. This method, apart from adding nodes, has the ability of moving and removing them. A comparison between the addition algorithms and the improved h-adaptive method has been performed. The best results has been obtained with the last one, which highlights the importance of moving and removing nodes and their application together to addition. With regard to the two options that we have handled in the addition algorithm in 3D, the first one works best when the error is distributed in larger regions while the second option works best when the error is more concentrated, as in the studied cases.

Both the automatic selection of the key parameters of the method and the h-adaptive method are very important in 3D where it is very difficult to work with irregular clouds of nodes that are very useful in many problems.

To conclude, we must point out that the clouds of nodes used in the cases presented in this paper have been made to extreme irregular situations and, although this kind of irregularity does not make sense in real cases, we have used it to apply the method under very adverse conditions.

Existence and uniqueness of solutions for a nonlocal fractional boundary value problem

Min Wang[1]

[1] *Department of Mathematics, Rowan University, Glassboro, NJ 08028, USA*

emails: wangmin@rowan.edu

Abstract

We study a nonlinear fractional boundary value problem with nonlocal boundary conditions. An associated Green's function is constructed as a series of functions by the perturbation approach. Criteria for the existence and uniqueness of solutions are obtained based on it.

Key words: Green's function, nonlocal boundary value problem, fractional calculus,
MSC 2000: primary 34B15; secondary 34B10

1 Introduction

In this paper, we study the boundary value problem (BVP) consisting of the fractional differential equation

$$-D_{0+}^{\alpha}u + a(t)u = w(t)f(u,s),\ 0 < t < 1,\ n-1 < \alpha < n,\ n \in \mathbb{N},\ n \geq 3, \tag{1}$$

and the nonlocal boundary condition (BC)

$$u^{(k)}(0) = 0,\ k = 0, 1, \ldots, n-1,\ u(1) = \int_0^1 u(s)dA(s), \tag{2}$$

where the following assumptions are satisfied:

(i) $a \in C[0,1]$, $w \in L[0,1]$ with $w(t) \not\equiv 0$ a.e. on $[0,1]$, and $f \in C(\mathbb{R} \times [0,1], \mathbb{R})$.

(ii) $A : [0,1] \to \mathbb{R}$ is a function of bounded variation and $\int_0^1 u(s)dA(s)$ denotes the Riemann-Stieltjes integral of u with respect to A.

 ISBN: 978-84-617-8694-7

(iii) $D^{\alpha}_{0+}h$ is the α-th Riemann-Liouville fractional derivative of h for $h : [0,1] \to \mathbb{R}$ defined by

$$D^{\alpha}_{0+}h(t) = \frac{1}{\Gamma(l-\alpha)}\frac{d^l}{dt^l}\int_0^t (t-s)^{l-\alpha-1}h(s)ds,\ l = \lfloor \alpha \rfloor + 1,$$

provided the right-hand side exists with Γ the Gamma function.

Remark 1.1 It is easy to see that the Riemann-Stieltjes integral in BC (2)

$$u(1) = \int_0^1 u(s)dA(s)$$

covers the multi-point and integral BCs as special cases.

Fractional differential equations have extensive applications in various fields of science and engineering. Many phenomena in viscoelasticity, electrochemistry, control theory, porous media, electromagnetism, and other fields, can be modeled by fractional differential equations. We refer to the reader [10, 13] and references therein for some applications.

The existence of solutions is an essential problem for BVPs of fractional differential equations. It has been studied by many authors, see [2–9, 11, 14] and references therein. Due to certain special properties of fractional calculus, critical point theory can only be applied to study equations involving both the left and right Riemann-Liouville fractional derivatives; see for example [1]. To the best of our knowledge, if only the left (or right) Riemann-Liouville fractional derivatives are involved, the only feasible approach to study the existence of solutions of a BVP is to convert the problem to an integral equation and use various techniques to find the fixed points.

The special case of BVP (1), (2) with $a(t) \equiv 0$ on $[0,1]$ has been studied by Zhang and Han [16] and Tan, Cheng, and Zhang [12]. Henderson and Luca [8] further studied a system of coupled nonlocal fractional BVPs. But the general case of BVP (1), (2) with $a \not\equiv 0$ has not been considered in the literature. It is notable that due to the unusual feature of the fractional calculus, even for a linear fractional BVP, it is not easy to find the solution when the equation contains multiple terms involving u or its derivative. For instance, to the best of our knowledge, there is no results on the solutions of the BVP involving the equation

$$-D^{\alpha}_{0+}u + a(t)u = h(t),$$

and the BC (2).

In this paper, we first utilize the perturbation approach developed in [4–7] to derive the Green's function for the BVP involving the equation

$$-D^{\alpha}_{0+}u + a(t)u = 0, \tag{3}$$

and BC (2) and then study the nonlinear BVP (1), (2) by the fixed point theory.

This paper is organized as follows: After this introduction, our main results are stated in Section 2. All the proofs are given in Section 3.

 ISBN: 978-84-617-8694-7

2 Main results

We first consider the Green's function for BVP (3), (2). The following notations are needed. Let $\Lambda \in \mathbb{R}$ and $G_0 \in C([0,1]\times[0,1],\mathbb{R})$ be defined by

$$\Lambda = \int_0^1 t^{\alpha-1} dA(t)$$

and

$$G_0(t,s) = \begin{cases} \dfrac{[t(1-s)]^{\alpha-1} - (t-s)^{\alpha-1}}{\Gamma(\alpha)}, & 0 \le s \le t \le 1, \\ \dfrac{[t(1-s)]^{\alpha-1}}{\Gamma(\alpha)}, & 0 \le t \le s \le 1. \end{cases}$$

Then define $\mathcal{G}_A : [0,1] \to \mathbb{R}$ by

$$\mathcal{G}_A(s) = \int_0^1 G_0(t,s) dA(t).$$

Throughout this paper, we assume

(H1) $0 \le \Lambda < 1$ and $\mathcal{G}_A(s) \ge 0$ on $[0,1]$.

Define

$$H_0(t,s) = \frac{t^{\alpha-1}}{1-\Lambda}\mathcal{G}_A(s) + G_0(t,s) \tag{4}$$

and

$$\overline{H}_0 = \frac{\max_{s\in[0,1]} |\mathcal{G}_A(s)|}{1-\Lambda} + \frac{1}{\Gamma(\alpha-1)}. \tag{5}$$

Remark 2.1 It is known that $H_0 \in C([0,1]\times[0,1],\mathbb{R})$ is the Green's function for BVP (3), (2) with $a \equiv 0$ and $H_0(t,s) \ge 0$ on $[0,1]\times[0,1]$ when (H1) holds; the reader is referred to [12, 16] for more properties of H_0.

Let $H : [0,1]\times[0,1] \to \mathbb{R}$ be defined by

$$H(t,s) = \sum_{n=0}^{\infty} (-1)^n H_n(t,s) \tag{6}$$

with H_0 defined above and $H_n : [0,1]\times[0,1] \to \mathbb{R}$, $n = 1, 2, \ldots$, defined by

$$H_n(t,s) = \int_0^1 a(\tau) H_0(t,\tau) H_{n-1}(\tau,s) d\tau, \quad n \ge 1.$$

We also need the following assumption:

 ISBN: 978-84-617-8694-7

(H2) $\overline{a} := \max_{t\in[0,1]} |a(t)| < \overline{H}_0^{-1}$ with $\overline{H}_0$ defined by (5).

Then we have the following result.

Theorem 2.1 *Assume (H1) and (H2) hold. Then H defined by* (6) *as a series of functions is uniformly convergent for $(t,s) \in [0,1]\times[0,1]$ and continuous on $[0,1]\times[0,1]$. Furthermore, H is the Green's function for BVP* (3), (2) *with*

$$|H(t,s)| \le \frac{\overline{H}_0}{1-\overline{a}\overline{H}_0}$$

on $[0,1]\times[0,1]$, where $\overline{H}_0$ is defined by (5).

With Theorem 2.1, we are ready to study the nonlinear BVP (1), (2). Let

$$U = \max_{t\in[0,1]} \int_0^1 |H(t,s)w(s)|ds, \tag{7}$$

where H is defined by (6). For any $u \in C[0,1]$, define $\|u\| = \max_{t\in[0,1]} |u(t)|$.

Theorem 2.2 *Assume (H1) and (H2) hold. If there exist $M > 0$ and $\kappa \in [0, U^{-1})$ such that*

$$\max_{(x,t)\in[-M,M]\times[0,1]} |f(x,t)| \le M/U, \tag{8}$$

and for any x_1, x_2 with $|x_i| \le M$, $i = 1,2$,

$$|f(x_1,t) - f(x_2,t)| \le \kappa|x_1 - x_2|, \qquad t \in [0,1], \tag{9}$$

then

(a) BVP (1), (2) *has a unique solution $u \in C[0,1]$ with $\|u\| \le M$.*

(b) For any $u_0 \in C[0,1]$ with $\|u_0\| \le M$, the sequence $\{u_n\}$ defined by

$$u_{n+1} = \int_0^1 H(t,s)w(s)f(u_n(s),s)ds, \qquad n = 0,1,2,\ldots,$$

satisfies $\|u_n - u\| \to 0$ as $n \to 0$.

The following result on the existence of solutions is obtained when a weaker condition than Theorem 2.2 is used.

Theorem 2.3 *Assume (H1) and (H2) hold. If there exist $M > 0$ and $\kappa \in [0, U^{-1})$ such that* (8) *holds, then BVP* (1), (2) *has at least one solution $u \in C[0,1]$ with $\|u\| \le M$.*

 ISBN: 978-84-617-8694-7

3 Proofs

The following lemma on the spectral theory in Banach spaces will be used to prove Theorem 2.1. See [15, page 795, items 57b and 57d] for the detail.

Lemma 3.1 *Let X be a Banach space, $\mathcal{A} : X \to X$ a linear operator with the operator norm $\|\mathcal{A}\|$ and the spectral radius $r(\mathcal{A})$ of $\mathcal{A}$. Then*

(a) $r(\mathcal{A}) \leq \|\mathcal{A}\|$;

(b) if $r(\mathcal{A}) < 1$, then $(\mathcal{I} - \mathcal{A})^{-1}$ exists and $(\mathcal{I} - \mathcal{A})^{-1} = \sum_{n=0}^{\infty} \mathcal{A}^n$, where $\mathcal{I}$ stands for the identity operator.

The following lemma is used to estimate the bounds of the Green's function H; see [12, Lemma 2.4] for details.

Lemma 3.2 *Assume (H1) holds. Then for any $(t, s) \in [0, 1] \times [0, 1]$,*

$$0 \leq \frac{t^{\alpha-1}\mathcal{G}_A(s)}{1-\Lambda} \leq H_0(t, s) \leq \overline{H}_0 t^{\alpha-1}, \tag{10}$$

where H_0 and $\overline{H}_0$ are defined by (4) and (5).

In the sequel, we let $X = C[0, 1]$ be the Banach space with the standard maximum norm.

Proof of Theorem 2.1. The proof is in the same spirit of the proofs of Theorem 2.1 and Lemma 3.3 in [5] using Lemmas 3.1, 3.2, and the fact

$$\left| \int_0^1 a(\tau) H_0(t, \tau) d\tau \right| \leq \int_0^1 \overline{a}\overline{H}_0 t^{\alpha-1} d\tau \leq \overline{a}\overline{H}_0 < 1.$$

We omit the details. □

Proof of Theorem 2.2. For any $u \in X$, define $T : X \to X$ by

$$(Tu)(t) = \int_0^1 H(t, s) w(s) f(u(s), s) ds, \tag{11}$$

where H is defined by (6). It is easy to see that T is completely continuous and u is a fixed point of T if and only if u is a solution of BVP (1), (2).

 ISBN: 978-84-617-8694-7

Let $K = \{u \in X \mid \|u\| \leq M\}$. For any $u \in K$ and $t \in [0,1]$,

$$|(Tu)(t)| = |\int_0^1 H(t,s)w(s)f(u(s),s)ds| \leq \int_0^1 |H(t,s)w(s)||f(u(s),s)|ds.$$

By (7) and (8),

$$|(Tu)(t)| \leq \int_0^1 |H(t,s)w(s)|\frac{M}{U}ds = M.$$

Therefore $\|Tu\| \leq M$, i.e. $TK \subset K$.

For any u_1 and $u_2 \in K$ and $t \in [0,1]$,

$$\begin{aligned}|(Tu_1)(t) - (Tu_2)(t)| =& |\int_0^1 H(t,s)w(s)\left[f(u_1(s),s)ds - f(u_2(s),s)\right]ds| \\ \leq& \int_0^1 |H(t,s)w(s)||f(u_1(s),s) - f(u_2(s),s)|ds.\end{aligned}$$

By (9),

$$\begin{aligned}|(Tu_1)(t) - (Tu_2)(t)| \leq& \int_0^1 |H(t,s)w(s)|\kappa|u_1(s) - u_2(s)|ds \\ \leq& U\kappa\|u_1 - u_2\| < \|u_1 - u_2\|.\end{aligned}$$

Hence $\|Tu_1 - Tu_2\| < \|u_1 - u_2\|$. Then parts (a) and (b) follow from the Banach Fixed Point Theorem. □

Theorem 2.3 is proved by Schauder's fixed point theorem. We omit the details.

Abstract

Flow and heat transfer in periodic structures are often encountered in many natural and industrial situations. In this work, the periodic features of fully developed periodic thermal flows have been implemented in the lattice Boltzmann method (LBM) for flow and heat transfer simulations. The unique particular dynamics in LBM is utilized and two numerical approaches, namely the distribution modification (DM) approach and the source term (ST) approach, are proposed. These methods can work with periodic thermal flows under either constant wall temperature (CWT) or surface heat flux (SHF) boundary conditions. Several example simulations are conducted, including flows through flat and wavy channels and flows through a square array with circular cylinders. Results are compared to analytical solutions, previous studies, and our own LBM calculations using different simulation techniques; and good agreement has been observed. These simple however representative simulations demonstrate the accuracy and usefulness of our proposed LBM methods for future thermal periodic flow simulations.

Key words: Lattice Boltzmann Method, Heat Transfer, Mass Transfer, Periodic Flow, Boundary Condition

1 Introduction

Periodic structures are often encountered in heat exchangers and other heat transfer systems, such as wavy or grooved pipes, fin-pin cold plates, and cross-flow heat exchangers [9, 10]. When fluid property changes neglected, identical flow field and similar temperature distributions can be observed in consecutive periodic modules after some distance from the entrance. The flow is then called fully developed in both flow and thermal fields [13, 6]. Numerous studies have been conducted on this topic; among them, existing simulations

 ISBN: 978-84-617-8694-7

mainly used traditional numerical techniques such as the finite-difference and finite-volume methods [13, 11, 15, 6, 1, 2].

Over the past two decades, the lattice Boltzmann method (LBM) has experienced significant development. In addition to various flow systems, LBM has also been successfully adopted to study other processes and phenomena, such as heat and mass transfer and electric and magnetic fields [7, 16, 19]. Unlike other traditional numerical schemes such as the finite-element, finite-difference, and finite-volume methods, where the governing equations of macroscopic properties are discretized mathematically, LBM works with a set of density distributions at each lattice node, and the evolution of these density distributions follows a simple collision-propagation process consecutively. Interestingly, macroscopic equations (such as the continuity and momentum equations for fluid dynamics, the convection-diffusion equation for heat and mass transfer, and the Poisson equation for electric fields) can be correctly recovered from the density distribution dynamics via mathematical analysis [7, 16]. Studies and applications have shown that LBM has some advantages over other methods in simulating multiphase flows, incorporating complex boundary geometries and moving boundaries, and implementing for parallel computation. Moreover, the particulate nature of LBM density distributions provides great convenience for applying periodic and symmetric (also including the free-slip boundary condition in fluid flows and the adiabatic boundary condition in heat transfer) boundary conditions along a lattice grid line, by simply *recycling* or *reflecting* the density distributions that cross the domain boundaries [16, 19]. Both periodic and symmetric boundary treatments have been frequently used in LBM flow simulations; however, this technical merit has not been recognized for LBM simulations of heat transfer processes in periodic flows yet.

In this paper, we extend the pressure periodic boundary method by Zhang and Kwok [20] to fully developed periodic thermal flows with constant wall temperature (CWT) or surface heat flux (SHF) boundaries. The similarity features of temperature field in periodic modules in such systems are first discussed; and then the double distribution LBM method for heat transfer is briefly outlined for readers′ convenience. Two different numerical approaches, the distribution modification (DM) and the source term (ST) approaches, are developed to incorporate these similarity features in LBM simulations. At last, several validation and demonstration simulations are performed to illustrate the correctness, accuracy, and usefulness of our proposed methods in LBM simulations of periodic thermal flows.

2 Theory and Methods

In this section we first describe in detail the periodic features of flow and temperature in fully developed periodic flows for both the CWT and SHF conditions, and then provide an outline of the LBM algorithm we use in this study. Such information is well documented in the literature; and we re-present these materials here for the completeness of this paper and

 ISBN: 978-84-617-8694-7

for the convenience of the following discussions of our new periodic boundary treatments.

2.1 Fully Developed Periodic Thermal Flows

The flow and temperature fields are governed by the following continuity (Eq. 1), momentum (Eq. 2), and energy (Eq. 3) equations:

$$\frac{\partial \rho}{\partial t} + \rho \nabla \cdot \mathbf{u} = 0 \quad , \tag{1}$$

$$\frac{\partial \mathbf{u}}{\partial t} + \nabla \cdot (\mathbf{u}\mathbf{u}) = -\frac{\nabla P}{\rho} + \nu \nabla^2 \mathbf{u} \quad , \tag{2}$$

$$\frac{\partial T}{\partial t} + \mathbf{u} \cdot \nabla T = \alpha \nabla^2 T \quad , \tag{3}$$

where $\mathbf{u}$ is the flow velocity, P is the pressure, T is the temperature, ρ is the fluid density, ν is the kinematic fluid viscosity, α is the fluid thermal diffusivity, and t is time. Here we have neglected the viscous dissipation term in the energy equation as in typically heat transfer research. When the flow is fully developed along the periodic passage, the velocity $\mathbf{u}$ becomes identical at locations of the same relative position in each periodic module (we will call them image locations hereafter); however, the pressure decreases for a certain amount over a module [13, 15]. Patankar et al. [13] then split the fluid pressure P into two components $P(x, y) = -\frac{\Delta P_L}{L} x + \widetilde{P}(x, y)$, and the momentum equation Eq. (2) is rewritten to

$$\frac{\partial \mathbf{u}}{\partial t} + \nabla \cdot (\mathbf{u}\mathbf{u}) = -\frac{\nabla \widetilde{P}}{\rho} + \nu \nabla^2 \mathbf{u} + \frac{\Delta P_L}{\rho L} \quad . \tag{4}$$

Now the flow system can be solved with an appropriate numerical method under a perfect periodic boundary condition across a module.

As for the temperature field, the periodic features depend on the boundary conditions imposed on the walls. For fully developed periodic thermal flows to be established, the solid surfaces must have a uniform, constant wall temperature (CWT) T_w, or they can have specified surface heat flux (SHF). For the latter situation, the heat flux could be uniform or varying over the surface within one module, but it must have the same distribution for all units. For the CWT systems, usually we first shift the temperature field by the wall temperature T_w to a reduced temperature $\theta = T - T_w$, and the energy equation Eq. (3) becomes

$$\frac{\partial \theta}{\partial t} + \mathbf{u} \cdot \nabla \theta = \alpha \nabla^2 \theta \quad ; \tag{5}$$

with the wall boundary condition for θ as $\theta(\Omega) = 0$ (here Ω denotes the wall surface). The periodic relationship for θ among modules is expressed as

$$\theta(x \pm mL, y) = e^{-\lambda_L (\pm mL)} \theta(x, y) \quad , \tag{6}$$

 ISBN: 978-84-617-8694-7

where λ_L is the decaying rate that describes the overall temperature variation in the streamwise direction [15]. Stalio and Piller [15] then introduced a normalized temperature $\bar{\theta} = \theta / e^{-\lambda_L x}$; and the energy equation for $\bar{\theta}$ becomes

$$\frac{\partial \bar{\theta}}{\partial t} + \mathbf{u} \cdot \nabla \bar{\theta} = \alpha \nabla^2 \bar{\theta} + (\alpha \lambda_L^2 + \lambda_L u_x)\bar{\theta} - 2\alpha \lambda_L \frac{\partial \bar{\theta}}{\partial x} \tag{7}$$

with an exact periodic boundary condition. In Eq. (7), u_x represents the x component of the flow velocity vector $\mathbf{u}$. The decaying rate λ_L can be determined from the energy balance as

$$\lambda_L = -\ln \left[1 - \alpha \int_\Omega \left(\frac{\partial \theta}{\partial n} \right) ds \Big/ \int_{in} \left(u_x \theta + \alpha \frac{\partial \theta}{\partial x} \right)_{in} dy \right] / L \quad . \tag{8}$$

Compared to the calculation method in Ref. [15], our method does not require volumetric integration over the entire simulation domain, which could be computational expensive especially in three-dimensional simulations.

For SHF systems, the periodic relationship for temperature is given as

$$T(x \pm mL, y) = T(x, y) \pm m \Delta T_L \quad ; \tag{9}$$

Here ΔT_L is the temperature change over a periodic unit and it is constant along the flow. Accordingly, Patankar et al. [13] defined a reduced temperature $\widetilde{T}(x, y) = T(x, y) - \frac{\Delta T_L}{L} x$ to achieve a perfect periodic boundary condition for $\widetilde{T}$. The energy equation should be rewritten correspondingly to

$$\frac{\partial \widetilde{T}}{\partial t} + \mathbf{u} \cdot \nabla \widetilde{T} = \alpha \nabla^2 \widetilde{T} - \frac{u_x \Delta T_L}{L} \quad . \tag{10}$$

The temperature change ΔT_L can be relatively easily found from the energy conservation principle:

$$\Delta T_L = \frac{\int_\Omega q ds}{\rho c \int_{in} u_{x,in} dy} \quad , \tag{11}$$

i.e., the temperature change equals the total thermal energy addition via the surface divided by the product of flow rate and volumetric heat capacity (ρc). Here q is the local heat flux entering the fluid domain via the boundary walls.

2.2 Double Distribution Thermal LBM Model

Next we describe the double-distribution lattice Bhatnagar-Gross-Krook (LBGK) model for thermal flows [8], although other LBM models are available in the literature [16, 7]. Here two sets of density distribution functions are employed: one as f_i for the fluid dynamics

 ISBN: 978-84-617-8694-7

and one as h_i for the thermal convection-diffusion equation. The collision step for these distributions can be expressed mathematically as

$$f_i^*(\mathbf{x},t) = f_i(\mathbf{x},t) - \tfrac{1}{\tau_f}\left[f_i(\mathbf{x},t) - f_i^{eq}(\mathbf{x},t)\right] + \delta f_i \quad , \tag{12}$$

$$h_i^*(\mathbf{x},t) = h_i(\mathbf{x},t) - \tfrac{1}{\tau_h}\left[h_i(\mathbf{x},t) - h_i^{eq}(\mathbf{x},t)\right] + \delta h_i \quad . \tag{13}$$

The relaxation parameters τ_f and τ_h are related to the respective transport coefficients and the additional terms δf_i and δh_i are used to recover the correct macroscopic equations. The fluid density ρ, equilibrium velocity $\mathbf{u}^{eq}$, and energy scalar A (could be the regular temperature T or its modified counterparts like $\widetilde{T}$, θ, or $\bar{\theta}$, depending on which energy equation to solve by distributions h_i) can be obtained from the density distributions f_i and h_i as

$$\rho = \sum_i f_i \ , \quad \mathbf{u}^{eq} = \sum_i f_i \mathbf{c}_i / \sum_i f_i \ , \quad A = \sum_i h_i \quad , \tag{14}$$

where $\mathbf{c}_i$ is the i-th lattice velocity. The equilibrium distributions f_i^{eq} and h_i^{eq} can then be calculated from these properties as [7, 4, 5]

$$f_i^{eq} = \omega_i \rho \left[1 + \frac{\mathbf{c}_i \cdot \mathbf{u}}{c_s^2} + \frac{(\mathbf{c}_i \cdot \mathbf{u})^2}{2c_s^4} - \frac{\mathbf{u}^2}{2c_s^2}\right] \quad , h_i^{eq} = A f_i^{eq}/\rho \quad . \tag{15}$$

The parameter ω_i is called the lattice weight factor and c_s is the lattice sound speed. After the collision, the post-collision distributions f_i^* and h_i^* will then move to the nearest neighboring lattice node at velocity $\mathbf{c}_i$ over a time step δt:

$$f_i(\mathbf{x} + \mathbf{c}_i \delta t, t + \delta t) = f_i^*(\mathbf{x},t) \quad ; h_i(\mathbf{x} + \mathbf{c}_i \delta t, t + \delta t) = h_i^*(\mathbf{x},t) \quad . \tag{16}$$

Appropriate mathematical analysis like the Chapman-Enskog expansion can be performed to the above distribution dynamics, and the following macroscopic equations can be derived [7, 16]:

$$\frac{\partial \rho}{\partial t} + \rho \nabla \cdot \mathbf{u} = 0 \quad , \tag{17}$$

$$\frac{\partial \mathbf{u}}{\partial t} + \nabla \cdot (\mathbf{u}\mathbf{u}) = -\frac{\nabla P}{\rho} + \nu \nabla^2 \mathbf{u} + \mathbf{F} \quad , \tag{18}$$

$$\frac{\partial A}{\partial t} + \mathbf{u} \cdot \nabla A = \alpha \nabla^2 A + S \quad . \tag{19}$$

The fluid properties $\mathbf{u}$, P, ν, and α are related to the LBM parameters by

$$\mathbf{u} = \mathbf{u}^{eq} + \frac{\mathbf{F}\delta t}{2\rho} \ , \quad P = c_s^2 \rho \ , \quad \nu = c_s^2 \left(\tau_f - \frac{1}{2}\right)\delta t \ , \quad \alpha = c_s^2 \left(\tau_h - \frac{1}{2}\right)\delta t \ . \tag{20}$$

The additional terms δf_i and δh_i in Eqs. (12) and (13) are related, respectively, to the forcing term $\mathbf{F}$ and source term S in the resulting macroscopic equations Eqs. (18) and (19) as

$$\delta f_i = \frac{\omega_i \mathbf{F} \cdot \mathbf{c}_i \delta t}{c_i^2} \ , \quad \delta h_i = \omega_i S \quad . \tag{21}$$

 ISBN: 978-84-617-8694-7

These δf_i and δh_i terms can be conveniently adjusted according to the forcing or source terms in the macroscopic equations to be solved. In our next validation and demonstration simulation examples, we use the simple D2Q9 (2D and $b = 9$) square lattice structure, for which the nine lattice velocities are

$$\mathbf{c}_0 = \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \quad \mathbf{c}_{1-4} = \begin{bmatrix} \cos(i-1)\pi/2 \\ \sin(i-1)\pi/2 \end{bmatrix} \frac{\delta x}{\delta t}, \quad \mathbf{c}_{5-8} = \sqrt{2} \begin{bmatrix} \cos(2i-9)\pi/4 \\ \sin(2i-9)\pi/4 \end{bmatrix} \frac{\delta x}{\delta t} \quad . \tag{22}$$

The lattice weight factors are $\omega_0 = 4/9$, $\omega_{1-4} = 1/9$, and $\omega_{5-8} = 1/36$; and the lattice sound speed $c_s = 1/\sqrt{3}\delta x/\delta t$. δx is the lattice grid resolution.

2.3 Simulating Periodic Thermal Flows with LBM

2.3.1 For Flow Field

Under a given pressure drop ΔP_L per periodic module, it is convenient to use the reduced pressure $\widetilde{P}$, and the LBM equations for f_i given in Section 2.2 can then be used $\mathbf{F} = (\Delta P_L/\rho L, 0)^T$. The classical periodic boundary condition [19] can then be applied at the periodic boundaries, meaning density distributions leaving the domain outlet will re-enter the domain at the inlet, or vice versa. This method has been widely used in LBM simulations, although more dedicate treatments are available to impose the pressure drop directly for some particular situations like multiphase or multicomponent flows [20]. To simulate a periodic flow with a specific flow rate, the pressure drop ΔP_L can be dynamically adjusted according to the simultaneous flow rate till the desirable value is established.

2.3.2 For Thermal Field: The Source Term (ST) Approach

Similarly, by tuning the source term δh_i according to Eq. (21), the LBM algorithm for h_i in Sect. 2.2 can be used to solve Eq. (7) for CWT systems

$$\delta h_i = \omega_i \left[(\alpha \lambda_L^2 + \lambda_L u_x)\bar{\theta} - 2\alpha\lambda_L \frac{\partial \bar{\theta}}{\partial x} \right] \tag{23}$$

for energy scalar $A = \bar{\theta}$; or to solve Eq. (10) for SHF cases with

$$\delta h_i = -\omega_i u_x \Delta T_L / L \tag{24}$$

for energy scalar $A = \widetilde{T}$. The temperature change ΔT_L for SHF cases can be readily calculated from the total heat flux over surface via Eq. (11); however, for CWT systems, the decaying rate λ_L is unknown before the simulation. In our practice, we start with an initial guess and run the simulation for some time (2000 time steps in our simulations) with that initial value. After that, a new λ_L value is calculated via Eq. (8) every certain time steps (we use 20 time steps), till the simulation becomes steady in flow and temperature fields. The differential term $\partial\bar{\theta}/\partial x$ in Eq. (7) can be estimated by a finite difference approximation.

 ISBN: 978-84-617-8694-7

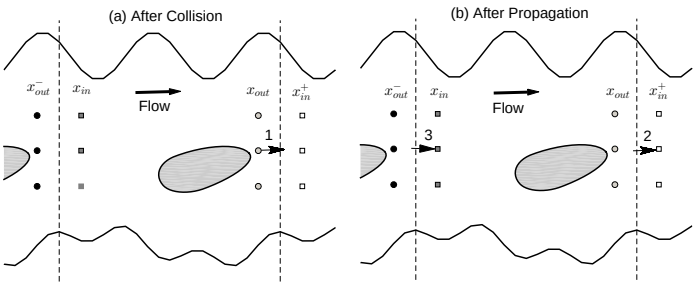

Figure 1: Schematic illustrations of the modified periodic boundary treatment for thermal field.

2.3.3 For Thermal Field: The Distribution Modification (DM) Approach

Another way to incorporate the periodic features of the temperature field described in Sect. 2.1 is to modify those density distributions h_i that cross the module inlet or outlet boundaries, as done in Ref. [20] for pressure periodic boundary conditions. We consider the CWT situation the periodic system shown in Fig. 1 with the first column of lattice nodes at x_{in} (dark gray squares) and the last column at x_{out} (light gray circles). Also displayed there are the outlet nodes of the upstream module at $x_{out}^- = x_{in} - \delta x = x_{out} - L$ (black circles) and the inlet nodes of the downstream module at $x_{in}^+ = x_{in} + L = x_{out} + \delta x$ as (white squares); although these nodes are actually not involved in the LBM calculation. To avoid the extra source term in Eq. (7), we will use LBM to solve the energy equation Eq. (5) for θ. Now let us take the post-collision distribution $h_1^*(x_{out})$ at x_{out} (Arrow 1 in Fig. 1a) as an example. In the propagation step, $h_1^*(x_{out})$ is supposed to move to the next node in velocity $\mathbf{c}_1 = (1, 0)^T$, and becomes the incoming distribution at the inlet node of the downstream module x_{in}^+ (Arrow 2 in Fig. 1b). However, now it is out of our simulation domain and therefore cannot participate in the LBM calculation anymore. On the other side, we need the incoming distribution $h_1(x_{in})$ at the domain inlet x_{in} (Arrow 3 in Fig. 1b), but it is not available since the nodes at the x_{out}^- are not in the simulation domain either. Based on the periodic relationship of temperature given in Eq. (6) and $\theta = \sum_i h_i$ (Eq. 14 with $A = \theta$), it is reasonable to assume the proportionality in θ can be extended to each distribution h_i, and therefore one has

$$h_1(x_{in}, t + \delta t) = e^{\lambda_L L} h_1(x_{in}^+, t + \delta t) = e^{\lambda_L L} h_1^*(x_{out}, t) \quad . \tag{25}$$

This analysis can be applied to other lattice distributions that cross the periodic boundaries during the propagation step, and a modified periodic boundary treatment for these distributions can be established as (for the D2Q9 lattice model used here)

$$h_i(x_{in}, y_{in}, t + \delta t) = e^{\lambda_L L} h_i^*(x_{out}, y_{out}, t) \quad , \quad y_{in} = y_{out} + c_{i,y}\delta t, \quad i = 1, 5, 8 \quad ; \tag{26}$$

 ISBN: 978-84-617-8694-7

$$h_i(x_{out}, y_{out}, t+\delta t) = e^{-\lambda_L L} h_i^*(x_{in}, y_{in}, t) \quad , \quad y_{out} = y_{in} + c_{i,y}\delta t, \quad i = 3, 6, 7 \quad . \tag{27}$$

Here $c_{i,y}$ is the $y-$component of the lattice velocity $\mathbf{c}_i$.

This distribution modification (DM) approach is also applicable to the SFH cases. Here we work with the original energy equation Eq. (3) and re-write the periodic relationship for the regular temperature T Eq. (9) to define a proportional factor β as

$$\beta = \frac{T(x_{in}^+)}{T(x_{in})} = 1 + \frac{\Delta T_L}{T(x_{in})} \quad ; \tag{28}$$

and, following the above discussion, the modified periodic boundary condition for h_i in SHF systems is

$$h_i(x_{in}, y_{in}, t+\delta t) = \beta^{-1} h_i^*(x_{out}, y_{out}, t) \quad , \quad y_{in} = y_{out} + c_{i,y}\delta t, \quad i = 1, 5, 8 \quad ; \tag{29}$$

$$h_i(x_{out}, y_{out}, t+\delta t) = \beta h_i^*(x_{in}, y_{in}, t) \quad , \quad y_{out} = y_{in} + c_{i,y}\delta t, \quad i = 3, 6, 7 \quad . \tag{30}$$

Note these modified periodic treatments revert back to the classical periodic boundary condition in LBM when the proportional factor $e^{-\lambda_L}$ or β is set to 1.

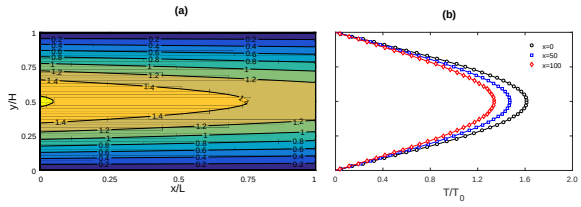

Figure 2: The simulated temperature field (a) and transverse profiles (b) for flow through the flat channel with CWT condition on the channel surfaces. In (b) the symbols are our LBM results and the underlying curves are from the analytical solution by Brown [3].

3 Validation and Demonstration Simulations

3.1 Heat Transfer of Laminar Flow through 2D Flat Channel

The fully developed flow in a uniform pipe or channel can be considered as an extreme example of periodic flows, for which the periodic module can be selected as a segment of the channel of any length. Here our simulation domain is a 2D rectangle of length $L = 200$

 ISBN: 978-84-617-8694-7

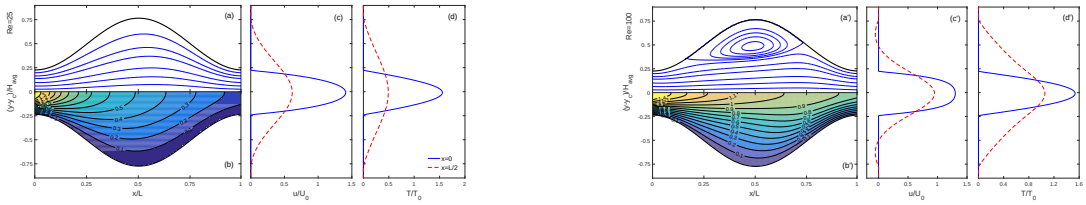

Figure 3: The simulated flow (a and a′) and temperature (b and b′) fields and transvers profiles of the streamwise velocity (c and c′) and temperature (d and d′) at two locations $x = 0$ and $x = L/2$ for the flows through a wavy channel with Reynolds number $Re = 25$ (a-d) and $Re = 100$ (a′-d′).

and height $H = 50$ (Both L and H, as well as other LBM parameters to be given in this section, are all non-dimensional values). The midpoint boundary method recently developed by Zhang and co-workers [18, 4, 5] is implemented at the solid-fluid boundaries for both flow and thermal LBM calculations for all simulations in this paper. The Reynolds number $Re = U_0 H/\nu$ is 40 (U_0 is the mean flow velocity) and the Prandlt number $Pr = \nu/\alpha$ is 0.7. The CWT situation is considered here and wall temperature T_w is set as 0; thus the regular temperature T and the reduced temperature θ are the same. During the simulation, the mean flow temperature at the domain inlet $T_0 = T_m(x = 0)$ is maintained at 1. This is the so-called Graetz problem, and the analytical solution can be expressed in series [3]. Fig. 2 shows the comparison between our LBM results using the DM periodic boundary method and those from Brown′s analytical solution [3] for the temperature field. No visible discrepancy can be observed. According to the analytical solution [3], the Nusselt number along the channel is constant at 3.7704; while our LBM yields an indeed constant value of 3.7757. The relative difference is only 0.14%, and we attribute it to the second-order finite difference approximation we use to evaluate the temperature gradient on surfaces.

3.2 Heat Transfer of Laminar Flow through 2D Wavy Channel

The flow and heat transfer through wavy channels have been extensively investigated for its practical applications [15, 17, 11, 2, 14]. As in the flat channel simulation, we have T_w=0, T_0=1, and Pr=0.7; and the DM method is used to incorporate the boundary periodicity. Two values, $Re = 25$ and 100, are tested in our simulations. Fig. 3 collects our LBM results of these two calculations, including the flow streamlines, the isotherms, and the spanwise profiles of streamwise velocity u_x and temperature T at the maximum and minimum width locations. The streamline and isotherm patterns are very similar to those reported in previous studies [2, 14]; however, a direct comparison is difficult due to the lack of original data for those publications. At $Re = 100$, a pair of circulation vortex have developed in the

 ISBN: 978-84-617-8694-7

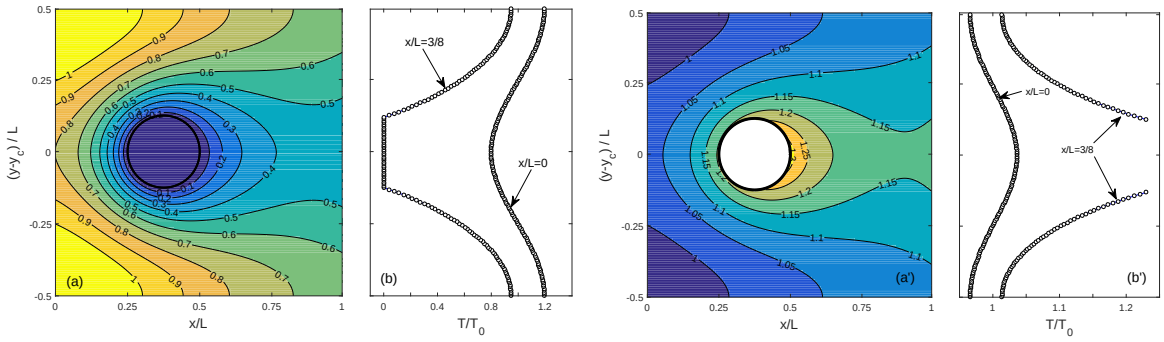

Figure 4: Result comparison of the simulations for the thermal flows around cylinder using the DM or ST approaches for the CWT (a and b) and SHF (a′ and b′) wall conditions. In the temperature fields (a and a′), the color patches are from the DM approach, and the isotherm lines are from the ST approach. The temperature profiles at $x/L = 0$ and $3/8$ (indicated by labels) are displayed in (b) and (b′), with the symbols from the DM approach and curves from the ST approach.

wide section, and the separation and reattachment locations are similar to those in Ref. [2].

3.3 Heat Transfer in Flow through Square Cylinder Array

The last system we simulate represents the heat transfer process associated to laminar flow through a square array of circular cylinders, which resembles the interior configuration of a cross-flow tube heat exchanger [9, 10]. The periodic module here is a square with $L = H = 160$, and the cylinder has a diameter of $D = 40$ and its center locates at $(3L/8, L/2)$. The flow direction is from the left to the right in the x-direction, and the regular periodic boundary condition is applied along the top and bottom edges. The Reynolds number $Re = U_0 H/\nu = 2.4$ and the Prandlt number $Pr = 1$. Four individual simulations are conducted: CWT+DM (the same one-module simulation above), CWT+ST, SHF+DM, and SHF+ST. To impose a desirable temperature gradient on the surface, the Neumann boundary method developed by Oulaid and Zhang [12] is employed. With the inlet mean temperature $T_0 = 1$ and wall temperature $T_w = 0$, the CWT case represents a cooling process. On the other hand, for SHF case, we use a uniform surface flux with $\partial T/\partial n = -0.01$ for the cylinder surface and it therefore is a heating process. Results from these simulations, including the temperature field in the domain and two representative transverse temperature profiles, are collected in Fig. 4. Figs. 4 a and a′ clearly show the cooling or heating effect from the cylinder on the fluid. It is interesting to see that, in Fig. 4a′ for the SHF boundary situation, the temperature increases near the outlet. This is understandable since the outlet

 ISBN: 978-84-617-8694-7

is close to the heating source (the cylinder) in the next module, and for this diffusion-dominant system (Peclet number $Pe = RePr = 2.4$), the heating flux from the cylinder can reach a relatively long distance even against the flow direction. As for the results from the DM or ST approaches for both CWT and SHF boundary conditions, one can see again excellent agreement exists in Fig. 4, and no apparent difference can be spotted. The decaying rate λ_L value is 3.88554×10^{-3} from the DM approach, and 3.88533×10^{-3} from the ST approach. Such a nearly perfect match indicates that both the DM and ST approaches can produce reliable results for simulating developed periodic thermal flows.

4 Summary and Concluding Remarks

We have examined the periodic relationships in flow and temperature fields for fully developed periodic thermal flows with CWT and SHF boundary conditions, and proposed two LBM implementations (the ST and DM approaches) for such flow situations. The methods have then been tested thoroughly in several simulations by comparing our LBM results to those from analytical solutions, previous publications, and our own LBM simulations using different numerical techniques. The good performance suggests that our methods could be useful for future LBM thermal simulations.

For the two numerical schemes to implement the periodic features of temperature in LBM, the ST approach has been typically used in traditional CFD studies, and certainly can also be adopted in LBM. On the other hand, the DM approach is unique for LBM with some computational advantages. In the DM method, extra calculations are only required for the thermal distributions crossing the periodic inlet/outlet boundaries; but in the ST method, an extra term has to be calculated for all distributions and at all lattice nodes. Furthermore, for systems with CWT boundaries, the ST approach also needs to calculate the streamwise derivative of temperature ($\partial\bar{\theta}/\partial x$ in Eq. 7), and this could further increase the computational demand. The method in Eq. (8) to calculate the decaying rate λ_L does not requires a volumetric integration of temperature over the entire computational domain, and thus it could also be useful for improving the computational efficiency of LBM as well as other CFD methods.

Abstract

With each breath, the human body breathes in air but also particles, bacteria and viruses. Particles penetrating into the system are trapped on a layer of mucus and propelled by tiny hairlike structure, cilia, that line the airways. In this paper, we calculate the average velocity of mucus residing above the cilia, which is mainly expelled by the cilia movement. For slow flow problem, we apply Stokes equation to find the mucus velocity where the bottom boundary condition of fluid velocity is obtained from the porous layer in which the fluid flows by the movement of cilia. A mixed finite element method is used to find the average mucus velocity in a three-dimensional domain. The numerical result is compared with that calculated by D. J. Smith et al. [Bull. Math. Biol., 69: 289-327, 2007] (38.3 $\mu m/s$) with a good agreement.

Key words: Mixed finite element method, Stokes equations, Cilia, Lung, Mucus, Three-dimensional domain

1 Introduction

Fluid transport is one of the most important phenomena in many biological problems. One example of the fluid transport problems is the transport of mucus in the human respiratory system. In pulmonary pathways, the epithelium surface is coated by a layer of mucus, which is considered to be either a highly viscous or viscoelastic fluid. The mucous layer traps, transports, or sometimes chemically disarms undesirable chemical or biological agents and natural debris, and so to avoid contamination or infection, mucus must be continuously expelled from the pulmonary pathway. Such an expelling force consists of two mechanisms: the coupling between liquid and airflow (e.g. breathing/coughing) and the force

 ISBN: 978-84-617-8694-7

from metachronal waves generated by the coherent beating of cilia - small hairlike structures. The primary transport mechanism responsible for the removal of mucus and cellular debris from the lungs is the second mechanism, the so-called muco-ciliary clearance. Due to the increasing patients with lung disease having problems with the transport of mucus in airways, researchers in biological fields are interested to find the mucus velocity in the bronchus and bronchioles. In this work, we focus on the primary mechanism and calculate the mucus velocity due to the movement of cilia.

Studying about mucus had been presented in various aspects in literatures. For example, Cees P van der Schans [10] experimentally studied mucus transport in airways. He concluded that the muco-ciliary transport was mostly at the peripheral airways and airflow transport was at the central airways. For airways disease, airflow transport was an important alternative to muco-ciliary clearance. The laboratory observations of Matsui et al. [8] indicated that the PCL and the mucous layers seemed to move in unison, while with the removal of the mucous layer, fluid transport in the PCL layer alone was drastically reduced. Hironori [6] provided that the average velocity above the cilia tips was a parabolic profile with the maximum velocity at the tips of cilia. H. Matsui et al. [7] studied on the pathogenesis of cystic fibrosis (CF) airways infection and suggested a treatment method by using salt and water instead of the modulation of ionic composition. The mucus velocities for normal and CF cases were also provided. The mucus velocity for normals was $26 \pm 5\mu m/s$ and that for CF was $1.2 \pm 0.2\mu m/s$ for 24 hr after addition of 50 μl of phosphate-buffered saline (PBS) containing tracers. The mucus velocity depended on the tracers and time. For different tracers and time, the mucus velocity values were various. S. K. Lai [4] reviewed the macro- and microrheology of human mucus and provided that for macroscale mucus behaved as a non-Newtonian fluid what it acted as a low viscosity liquid at the nanoscale.

Figure 1 shows the muco-ciliary system consisting of three layers. The middle layer, in which the cilia beat, is known as the periciliary layer (PCL) where the fluid in this layer is called PCL fluid, and the upper layer consists of mucus. Mucus is secreted by goblet cells in the lower layer that are interspersed among the ciliated cells to trap particles getting into the body. To model the slow flow problem, we employ Stokes equation coupling with the incompressible flow equation to calculate the mucus velocity using a mixed finite element method.

Literatures mathematically calculated the mucus velocity by using various models and methods. For instant, W. Hofmann and B. Asgharian [3] used the asymmetric multiple-path models of the bronchial tree to calculated the mucociliary clearance velocities in bronchial airway generations. They found that in human tracheal the mucus velocity was 5.5 mm/min and decreased in roughly exponential expression with increasing airway generation number. W. L. Lee et al. [5] simulated the muco-ciliary trannsport process using the projection method combined with the immersed boundary method (IBM) to describe the ciliary beating patterns. The mean mucus velocity is plotted with the viscosity of the mucus, the number

 ISBN: 978-84-617-8694-7

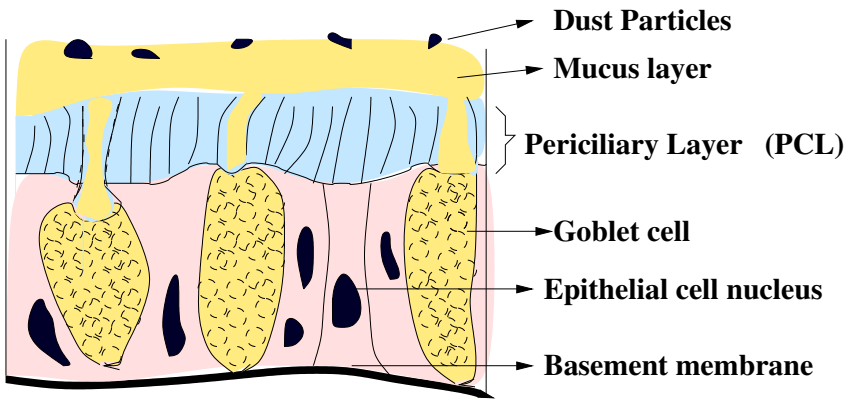

Figure 1: Schematic illustration the muco-ciliary system consisting of threee layers: epithelial layer, PCL and mucus layer.

of cilia, the depth of periciliary layer and the cilia beat frequency. D. J. Smith et al. [9] presented a new mathematical model, deriving from Navier-Stokes momentum equations, of the mucus transport in airways by cilia. They calculated the mean mucus speed, which is 38.3 $\mu m/s$. However, the literatures study only the case that the solid phases in PCL have no movement. In this article, we find the mucus velocity from the self-propelled of cilia in PCL. That is the boundary condition at the bottom of our numerical domain, mucus layer, is obtained from the PCL in which the PCL fluid is calculated from movement of cilia as provided in [2].

To calculate the numerical results, we employ the Stokes equations derived in [2] which will be briefly rewritten in Section 1 including the discretization of the model using a mixed finite element method written in [1] which will be rewritten here. In Section 3 we provide the boundary conditions obtained from [2] for coding where the numerical validation and results are presented in Section 4. The conclusion is drawn in Section 5.

2 Stokes Model and Its Discretization

In this section, we provide Stokes equation with the incompressible continuity equation and also its discretization using a mixed finite element method. The system of equation which is derived in [2] is as follows.

$$\nabla p - \mu \Delta \mathbf{v} = \rho \mathbf{g} \tag{1}$$

$$\nabla \cdot \mathbf{v} = 0, \tag{2}$$

 ISBN: 978-84-617-8694-7

where $\mathbf{v}$ is the velocity of the liquid phase; μ is the dynamic viscosity; p is pressure; $\mathbf{g}$ is gravity and ρ is fluid density.

Next, we transfer the Stokes model into discrete counterparts for making them suitable for numerical implementation. Although the model discretization has been provided in [1], they form an important part of our study. Then we briefly rewrite them here. Let Ω be our computational domain, T_h be a triangulation of domain Ω and

$$V_h = \{v \in H^1(\Omega) : v|_K \text{ is quadratic}, \forall K \in T_h\} \tag{3}$$

$$H_h = \{q \in L_0^2(\Omega) : q|_K \text{ is linear}, \forall K \in T_h\}, \tag{4}$$

be finite-dimensional subspaces of the Sobolev spaces $H^1(\Omega)$ and $L_0^2(\Omega)$, respectively, where

$$L_0^2(\Omega) = \{q \in L^2(\Omega) : \int_\Omega q d\Omega = 0\}. \tag{5}$$

By using a mixed finite element method provided in [1], the system of equations (1) - (2) can be written in the matrix form as

$$\begin{pmatrix} \tilde{\mathbf{B}} & 0 & 0 & -\tilde{\mathbf{Q}}_1^T \\ 0 & \tilde{\mathbf{B}} & 0 & -\tilde{\mathbf{Q}}_2^T \\ 0 & 0 & \tilde{\mathbf{B}} & -\tilde{\mathbf{Q}}_3^T \\ -\tilde{\mathbf{Q}}_1 & -\tilde{\mathbf{Q}}_2 & -\tilde{\mathbf{Q}}_2 & 0 \end{pmatrix} \begin{pmatrix} \mathbf{V}_1 \\ \mathbf{V}_2 \\ \mathbf{V}_3 \\ \mathbf{P} \end{pmatrix} = \begin{pmatrix} \tilde{\mathbf{B}}_1 \\ \tilde{\mathbf{B}}_2 \\ \tilde{\mathbf{B}}_3 \\ \mathbf{0} \end{pmatrix}, \tag{6}$$

where the approximate solutions $(v_i, p) \in V_h \times H_h$ are

$$v_i(\mathbf{x}) = \sum_{m=1}^{M} \psi_m(\mathbf{x}) v_i^m = \Psi^T \mathbf{V}_i, \tag{7}$$

$$p(\mathbf{x}) = \sum_{l=1}^{L} \phi_l(\mathbf{x}) p_l = \Phi^T \mathbf{P}. \tag{8}$$

where $\mathbf{V}_i$ and $\mathbf{P}$ are vectors of the velocities and pressure, respectively; ψ_m and ϕ_l are basis functions; Ψ and Φ are their vector forms and the integers M and L are determined by the interpolation function and

$$\tilde{\mathbf{B}} = (\mu/\epsilon^l)(\tilde{\mathbf{K}_{jj}}), \quad \tilde{\mathbf{K}_{ij}} = \int_{\Omega^e} \frac{\partial \Psi}{\partial x_i} \frac{\partial \Psi^T}{\partial x_j} d\Omega^e, \quad \tilde{\mathbf{Q}}_i = \int_{\Omega^e} \Phi \frac{\partial \Psi^T}{\partial x_i} d\Omega^e, \tag{9}$$

$$\tilde{\mathbf{B}}_i = \left(-\int_{\Gamma^e} \Psi \Phi^T n_i d\Gamma^e \right) \mathbf{P} + \frac{\mu}{\epsilon^l} \left(\int_{\Gamma^e} \Psi \frac{\partial \Psi^T}{\partial x_j} n_j d\Gamma^e \right) \mathbf{V}_i, i = 1, 2, 3. \tag{10}$$

The notation Ω^e indicates the element domain such that $\Omega = \bigcup_e \Omega^e$ and the repeated index j is the summation over $j, j = 1, 2, 3$.

 ISBN: 978-84-617-8694-7

3 Boundary conditions

In this section, we provide boundary conditions used to model the problem. First, we inspect the condition at the bottom of domain Ω. Since in this work we assume that the mucus flow depends on the cilia movement, we then begin by considering the PCL layer where the PCL fluid is moved by the ciliary beating provided in [2]. Therefore, the velocity of the PCL fluid at the tip of cilia becomes our boundary condition at the bottom of our numerical domain. Because K. Chamsri and L. Schreyer [2] assume that the cilia are an array of cylinders and the cilia move by making angles θ with the horizontal plane, to calculate the mucus velocity, they provide the average velocity over all angles at the top of PCL domain. Figure 2 shows the the boundary condition of the mean velocity at the bottom of our domain. The top one is the first component of the velocity and the middle and the bottom ones are the second and third components, respectively.

By employing the boundary conditions from [2], we now have the boundary condition at the bottom of our numerical domain. For other boundary conditions, they are written with the system of equations as follows.

$$\nabla p - \mu \Delta \mathbf{v} = \rho \mathbf{g} \qquad \text{in } \Omega \tag{11}$$

$$\nabla \cdot \mathbf{v} = 0, \qquad \text{in } \Omega \tag{12}$$

$$\mathbf{v} \text{ is employed from [2]} \qquad \text{at the bottom of } \Omega \tag{13}$$

$$\mathbf{v} \text{ and } p \text{ are periodic} \qquad \text{on the left and right sides.} \tag{14}$$

4 Numerical Validation and Results

The numerical solutions of the model and boundary conditions provided in Section 1 and 3, respectively, are presented in this section. By using the model discretization of Taylor-Hood type written in Section 1, for the case of average velocity of PCL at the tip of cilia or the bottom of mucus layer, the velocity of mucus presented in Figure 3 with 15,468 number of degree of freedom with CPU time about 1 month. The average mucous velocity is 31.67 $\mu m/s$. The result can be verified by comparing it with Matsui et al. [8] and Smith et al.[9]. Matsui et al. [8] experimentally shows a mean mucus transport of $39.8 \pm 4.2 \mu m/s$ and Smith et al. [9] presents a mean mucus velocity of 38.3 $\mu m/s$. The discrepancy between the solutions may be from the different assumptions and techniques used in the works. For instant, Smith et al. [9] considered the mucus layer and mucus-PCL interface as linear viscoelastic and completely flat, respectively by using a new mathematical model while Matsui et al. [8] assumed that the PCL is nearly stationary with human tracheobronchial cell cultures. Comparing our solution with them, it shows a reasonable agreement with our predicted value.

 ISBN: 978-84-617-8694-7

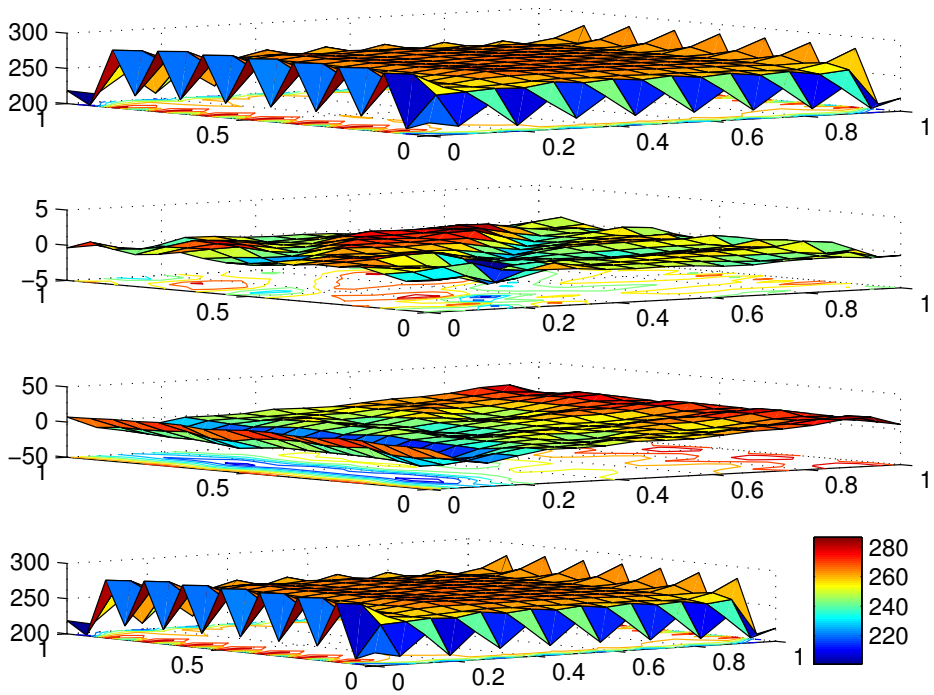

Figure 2: Boundary condition of the velocity at the bottom of our numerical domain in case of average velocity of PCL over all angles.

5 Conclusion

We calculate mucus velocity due to the movement of cilia consisting in the PCL. For the slow flow problem, we use Stokes equation on the domain of mucus layer. The boundary condition at the bottom of our numerical domain is employed from the velocity of PCL fluid at the top of PCL provided in [2]. The velocity is obtained from averaging the velocity of the PCL fluid over angles θ that cilia make with the horizontal plan. At the sides of our cube domain, periodic boundary conditions are applied and a mixed finite element method is exploited to determine the velocity profile. The average result over the z axis of the domain are compared with Matsui et al. [8] and Smith et al.[9]. The result is in good agreement.

Abstract

In the paper, we are concerned with the existence criteria of the solution to a class of Riemann-Liouville fractional Hamiltonian system. The variational structure of this Hamiltonian system is demonstrated by using the Hamiltonian action and the Legendre transform. As an applications, some new results on the existence of at least one periodic solution are obtained by means of the dual last action principle. The distinction of this paper from others is that the variational methods and the critical point theory are used to study the fractional Hamiltonian systems.

Key words: Fractional Hamiltonian systems, periodic solutions, variational structure, the dual last action principle.
MSC 2000: 34B25; 34B18; 35G30

1 Introduction

Fractional calculus finds its wide applications in many different fields, such as mathematical modeling of control theory, fluid flow, bioengineering, biochemistry, electrical networks, astronomy, viscoelasticity and other fields of science, see [1, 4] and references therein. Therefore, the theory of fractional differential equation is an area intensively developed during the last decades [3, 5]. The study techniques employed frequently are fixed point theory (including the Banach contraction mapping principle and the Schaefer fixed point theorem [7, 8, 15]), topological degree theory (coincidence degree theory [6]), comparison method (including upper and lower solutions and monotone iterative method [2, 9]), and so on. It should be noted that the study techniques employed in this paper are quite from the above.

 ISBN: 978-84-617-8694-7

The results, which have been obtained in this paper about the existence and multiplicity of solutions to nonlinear fractional differential equation, are derived by using the variational methods and the critical point theory.

Critical point theory has been proved to be very effective tools in determining the existence of solution to integer order Hamiltonian systems, please refer to [16]. The idea behind it is that finding solutions to a given Hamiltonian systems (boundary value problem) is equal to looking for critical points of a suitable energy functional defined on an appropriate function space. But till now, there are few results obtained on the solution to fractional Hamiltonian systems (boundary value problem), by the critical point theory[10–12], since it is often difficult to establish a suitable space and variational functional of fractional Hamiltonian systems.

In [10], Jiao and Zhou have studied the following fractional boundary value problem

$$\begin{cases} {}_tD_T^{\alpha}\left({}_0D_t^{\alpha}u(t)\right) = \nabla F\left(t,u(t)\right), \quad t\in[0,T], \\ u(0)=u(T)=0, \end{cases} \tag{1}$$

where ${}_tD_T^{\alpha}$ and ${}_0D_t^{\alpha}$ are respectively the right and left Riemann-Liouville fractional derivative of order $0<\alpha\leq 1$, $F:[0,T]\times\mathbb{R}^N\to\mathbb{R}$ is a given function satisfying some assumptions and $\nabla F\left(t,u(t)\right)$ is gradient of F at u. The authors have proved the existence of solutions to boundary value problem (1) by means of critical point theory.

Motivated by the results[10–12], we make study on the existence criteria for the following fractional Hamiltonian system

$$\begin{cases} {}_0D_t^{\alpha}\left({}_0D_t^{\alpha}u(t)\right) + \nabla F\left(t,u(t)\right) = 0, \ a.e. \ \ t\in[0,T], \\ u(0)=u(T)=0, \end{cases} \tag{2}$$

where $0<\alpha\leq 1$, $T>0$, $F:(t,u)\to F(t,u)$ measurable in t for every $u\in\mathbb{R}^N$ and continuously differentiable and convex in u for a.e. $t\in[0,T]$, $\nabla F\left(t,u\right)$ is gradient of F at u, and ${}_0D_t^{\alpha}$ is the left Riemann-Liouville fractional derivative of order $0<\alpha\leq 1$. The variational structure of Hamiltonian systems mentioned above is obtained by using the Hamiltonian action and the Legendre transform. As an applications, the existence of at least one periodic solution is demonstrated by using the dual last action principle. The distinction of this paper from others is that the variational methods and the critical point theory are used to study the fractional Hamiltonian systems.

Moreover, consider the following second-order Hamiltonian systems

$$\begin{cases} u''(t) + \nabla F\left(t,u(t)\right) = 0, \quad t\in[0,T], \\ u(0)=u(T)=0. \end{cases} \tag{3}$$

Here it is obvious that the problem on the existence of solution for the system (3) is closely related to the Hamiltonian systems (2), and if the choice of $\alpha=1$, system (2) leads to the system (3).

 ISBN: 978-84-617-8694-7

2 Preliminary

In this section, in order to apply critical point theory to the study of the existence of solutions to the fractional Hamiltonian systems (2), we list some basic definitions and Lemmas which are to be used in the proof of our main results. Some basic definitions and properties of fractional calculus which are used in this paper, please refer to [10, 13, 14].

Let us recall respectively the spaces R, L^p, $L^p[0,t]$, and the norms are defined separately by

$$\| x \|_\infty = \max_{t\in[0,T]} | x(t) |, \quad \| x \|_{L^p} = \left(\int_0^T | x(t) |^p \, ds\right)^{1/p}$$

and

$$\| x \|_{L^p[0,t]} = \left(\int_0^t | x(t) |^p \, ds\right)^{1/p},$$

where $t \in [0,T]$ and $1 < p < \infty$.

Definition 1. [10] Let $0 < \alpha \leq 1$ and $1 < p < \infty$, the fractional derivative space $E_0^{\alpha,p}$ is defined by the closure of $C_0^\infty([0,T],\mathbb{R}^N)$ with respect to norm

$$\| x \|_{\alpha,p} = \left(\int_0^T | x(t) |^p \, dt + \int_0^T | {}_0D_t^\alpha x(t) |^p \, dt\right)^{1/p} \text{ for any } x \in E_0^{\alpha,p},$$

where $C_0^\infty([0,T],\mathbb{R}^N)$ denotes the set of all functions $x \in C^\infty\left([0,T],\mathbb{R}^N\right)$ with $x(0) = x(T) = 0$

We shall denote by $\Gamma_0\left((\mathbb{R}^N\right)$ the set of all convex lower semi-continuous(l.s.c.) functions $F : \mathbb{R}^N \to [-\infty, +\infty]$, whose effective domain $D(F) = \{x \in \mathbb{R}^N : F(x) < +\infty\}$ is non-empty.

Definition 2. [14] Let $H : [0,T]\times\mathbb{R}^{2N} \to \mathbb{R}, (t,u) \to H(t,u)$ be a smooth Hamiltonian such that for each $t \in [0,T]$, $H(t,\cdot) \in \Gamma_0(\mathbb{R}^N)$ is strictly convex and $\frac{H(t,u)}{|u|} \to +\infty$ if $| u | \to +\infty$. The Fenchal (or Legendre) transform is defined by $H^*(t,v) = \sup_{u\in\mathbb{R}^{2N}} (v,u) - H(t,u)$, or

$$\begin{aligned} H^*(t,v) &= (v,u) - H(t,u), \\ v = \nabla H(t,u), \quad u &= \nabla H^*(t,v), \end{aligned} \tag{4}$$

Finally, we present some Lemmas which are used to prove our main results.

Lemma 1. [10, Proposition 3.1] *Let $0 < \alpha \leq 1$ and $1 < p < \infty$, then the fractional derivative space $E_0^{\alpha,p}$ is a reflexive and separable Banach space.*

Lemma 2. [14, Proposition 2.4] If $F \in \Gamma_0(\mathbb{R}^N)$ is strictly convex and such that $F(u)/ | u | \to +\infty$ if $| u | \to \infty$, then $F^* \in C^1(R^N,\mathbb{R})$.

 ISBN: 978-84-617-8694-7

Lemma 3. [10, Proposition 3.2] *Let $0 < \alpha \leq 1$ and $1 < p < \infty$. For all $x \in E_0^{\alpha,p}$, if $1 - \alpha \geq 1/p$ or $\alpha > 1/p$, we have*

$$\| x \|_{L^P} \leq \frac{T^\alpha}{\Gamma(\alpha+1)} \|_0 D_t^\alpha x \|_{L^P} . \tag{5}$$

If $\alpha > 1/p$ and $\frac{1}{p} + \frac{1}{q} = 1$, then

$$\| x \|_\infty \leq \frac{T^{\alpha-1/p}}{\Gamma(\alpha)((\alpha-1)q+1)^{1/q}} \|_0 D_t^\alpha x \|_{L^P} . \tag{6}$$

According to (5), we can consider $E_0^{\alpha,p}$ with respect to the norm

$$\| x \|_{\alpha,p} = \|_0 D_t^\alpha x \|_{L^p} = \left(\int_0^T |_0 D_t^\alpha x |^p \, dt \right)^{1/p} \tag{7}$$

in the following analysis.

Lemma 4. [10, Proposition 3.4] *Let $0 < \alpha \leq 1$ and $1 < p < \infty$. Assume that $\alpha > 1/p$ and the sequence u_k converges weakly to u in $E_0^{\alpha,p}$ i.e. $u_k \rightharpoonup u$, then $u_k \to u$ in $C([0,T], \mathbb{R}^N)$, i.e. $\| u - u_k \|_\infty = 0$ as $k \to \infty$.*

Lemma 5. [14, Theorem 1.1] *If φ is w.l.s.c. on a reflexive Banach space X and has a bounded minimizing sequence, then φ has a minimum on X.*

3 Variational structure

In this section, the variational structure of the fractional Hamiltonian systems (2) is derived by means of the Hamiltonian action and the Legendre transform, which enables us to convert the existence of solutions to fractional Hamiltonian systems (2) into finding the critical points of a corresponding functional.

Let the space X be defined by

$$X = \left\{ v = (v_1, v_2) : v_1 \in E_0^{\alpha,q}\left(0, T; \mathbb{R}^N\right), v_2 \in E_0^{\alpha,p}\left(0, T; \mathbb{R}^N\right) \right\},$$

and the norm is equipped with $\| v \| = \| v_1 \|_{\alpha,q} + \| v_2 \|_{\alpha,p}$. It follows from Lemma 1 that X is a reflexive Banach space.

Assume that $\widetilde{E}_0^{\alpha,p} = \{x \in E_0^{\alpha,p} : \int_0^T x(s)ds = 0\}$, then

$$\widetilde{X} = \left\{ v = (v_1, v_2) : v_1 \in \widetilde{E}_0^{\alpha,q}\left(0, T; \mathbb{R}^N\right), v_2 \in \widetilde{E}_0^{\alpha,p}\left(0, T; \mathbb{R}^N\right) \right\}.$$

Let $(E_0^{\alpha,p})^*$ be standed by the conjugate space of $E_0^{\alpha,p}$, there is

$$X^* = \left\{ v = (v_1, v_2) : v_1 \in (E_0^{\alpha,q})^*, v_2 \in (E_0^{\alpha,p})^* \right\},$$

 ISBN: 978-84-617-8694-7

and we easily know that X^* is the conjugate space of X.

Moreover, let the space Y be defined by

$$Y = \left\{ u = \left(u_1, u_2\right) : u_1 \in E_0^{\alpha,p}\left((0,T;\mathbb{R}^N\right), u_2 \in E_0^{\alpha,q}\left((0,T;\mathbb{R}^N\right)\right\},$$

Let $h \in L^1(0,T;\mathbb{R}^N)$, the mean value is defined by $\bar{h} = \frac{1}{T}\int_0^t h(t)dt$. We denote by $J = \begin{pmatrix} 0_N & I_N \\ -I_N & 0_N \end{pmatrix}$ the symplectic matrix, then $(Ju, v) = -(u, Jv)$ for all $u, v \in \mathbb{R}^{2N}$.

Let $x = u_1$, ${}_0D_t^\alpha x = \lambda u_2$, then, the fractional Hamiltonian systems (2) reduces to

$${}_0D_t^\alpha u_1 + \lambda u_2 = 0 \text{ and } u_i(0) = u_i(T) = 0, \quad i = 1, 2,$$

that is, the fractional Hamiltonian systems (2) is equivalent to the following non-autonomous fractional Hamiltonian systems

$$\begin{cases} J {}_0D_t^\alpha u + \nabla H(t,u) = 0, \\ u(0) = u(T) = 0, \end{cases} \tag{8}$$

where ${}_0D_t^\alpha u = \begin{pmatrix} {}_0D_t^\alpha u_1 \\ {}_0D_t^\alpha u_2 \end{pmatrix}, \nabla H(t,u) = \begin{pmatrix} \frac{1}{\lambda}\nabla F(t,u_1) \\ -\lambda u_2 \end{pmatrix}$. Therefore, the Hamiltonian action ψ can be written

$$\psi(u) = -\int_0^T \left[\tfrac{1}{2}(J {}_0D_t^\alpha u(t), u(t)) + H(t,u(t))\right] dt. \tag{9}$$

Setting ${}_0D_t^\alpha v = -J {}_0D_t^\alpha u$, so that

$$u = Jv - c. \tag{10}$$

According to (8) and (11), we have ${}_0D_t^\alpha v = \nabla H(t,u)$, if the Legendre transform $H^*(t,.)$ of $H(t,.)$ existence, then

$$u = \nabla H^*\left(t, {}_0D_t^\alpha v\right). \tag{11}$$

Hence, in terms of (10), the Hamiltonian equations (11) reduces to $Jv - \nabla H^*\left(t, {}_0D_t^\alpha v\right) = c$.

In the following, we prove that the Legendre transform $H^*(t,.)$ of $H(t,.)$ existence. It follow from (9) and (11) that

$$\begin{aligned} &\psi(u) = -\int_0^T \left[\tfrac{1}{2}(J {}_0D_t^\alpha u(t), u(t)) + H(t,u(t))\right] dt = \int_0^T \left[\tfrac{1}{2}({}_0D_t^\alpha v(t), u(t)) - H(t,u(t))\right] dt \\ &= \int_0^T \left[-\tfrac{1}{2}({}_0D_t^\alpha v(t), u(t)) + ({}_0D_t^\alpha v(t), u(t)) - H(t,u(t))\right] dt \\ &= \int_0^T \left[\tfrac{1}{2}(J {}_0D_t^\alpha u(t), u(t)) + ({}_0D_t^\alpha v(t), u(t)) - H(t,u(t))\right] dt. \end{aligned}$$

Formula (4) suggests replacing $({}_0D_t^\alpha v, u) - H(t,u)$ by $H^*(t, {}_0D_t^\alpha v)$. The dual action is thus defined on a suitable space of T-periodic functions by

$$\chi(v) = \int_0^T \left[\tfrac{1}{2}({}_0D_t^\alpha v(t), v(t)) + H^*(t, {}_0D_t^\alpha v(t))\right] dt,$$

where $v = \left(v_1, v_2\right), v_1, v_2 \in \mathbb{R}^N$. In Section 4, we shall see that χ can be bounded below under reasonable assumptions upon H. So it suffices to find critical points of χ restricted to the space $\widetilde{X}$.

 ISBN: 978-84-617-8694-7

Lemma 6. *Assume that $H : [0,T] \times \mathbb{R}^{2N} \to \mathbb{R}, (t,u) \to H(t,u)$ be measurable in t for each $u \in \mathbb{R}^{2N}$ and strictly convex and continuously differentiable in u for almost every $t \in [0,T]$. If there exists $q \in [1,\infty], \lambda > 0, \delta > 0, \beta, \gamma \in L^p(0,T;\mathbb{R}^+)$ with $\frac{1}{p} + \frac{1}{q} = 1$, such that for all $u \in \mathbb{R}^{2N}$ and a.e. $t \in [0,T]$, one has*

$$\delta(\mid u \mid^q /q) - \beta(t) \leq H(t,u) \leq \lambda(\mid u \mid^q /q) + \gamma(t). \tag{12}$$

Then the dual action χ is a continuously differentiable on $\tilde{X}$ and, if $v \in \tilde{X}$ is a critical point of χ, the function u defined by $u(t) = \nabla H^*(t, {}_0D_t^\alpha v(t))$ satisfies fractional Hamiltonian systems (8).

Proof. It follows from Lemma 2 that $H^*(t,u)$ is continuously differentiable in u for a.e. $t \in [0,T]$. By assumption (12), for all $u \in \mathbb{R}^{2N}$ and a.e. $t \in [0,T]$, we obtain

$$\lambda^{-p/q}(\mid v \mid^p /p) - \gamma(t) \leq H^*(t,v) \leq \delta^{-p/q}(\mid v \mid^p /p) + \beta(t). \tag{13}$$

Proposition 2.2 in [14] implies that

$$\mid \nabla H^*(t,v) \mid \leq [(q/\delta)(\mid v \mid) + \beta(t) + \gamma(t) + 1]^{p-1} \leq c_1 \mid v \mid^{p-1} + c_2(\beta(t) + \gamma(t) + 1)^{p-1},$$

for some positive constants c_1 and c_2.

Let us note that $(\beta+\gamma+1)^{p-1} \in L^q$ since $(\beta+\gamma+1) \in L^p$. By (13) and (14), the function L defined by $L(t,x,y) = (1/2)(Jy,x) + H^*(t,y)$ satisfies the assumptions of Theorem 3.1 in [10]. Therefore, the dual action χ is continuously differentiable on X, and, hence, on $\tilde{X}$.

Finally, if $v \in \tilde{X}$ is a critical point of χ, Theorem 3.1 in [10] implies that, for all $h \in \tilde{X}$, one has

$$0 = \int_0^T \left[\tfrac{1}{2}(J_0D_t^\alpha v(t), h(t)) + (\nabla H^*(t, {}_0D_t^\alpha v(t)) - \tfrac{1}{2}Jv(t), {}_0D_t^\alpha h(t))\right] dt. \tag{14}$$

It is then easy to verify the preceding relation for all $h \in X$, and hence for all $h \in C_T^\infty$. By (14), we have

$$\nabla H^*(t, {}_0D_t^\alpha v(t)) - \tfrac{1}{2}Jv(t) = \int_0^t \tfrac{1}{2}J_0D_t^\alpha v(s)ds + c, \text{ a.e. on } [0,T],$$

i.e., $Jv(t) = \nabla H^*(t, {}_0D_t^\alpha v(t)) + \tilde{c}$, a.e. on $[0,T]$. Setting $u(t) = H^*(t, {}_0D_t^\alpha v(t)) = Jv(t) - \tilde{c}$, we obtain $u \in X$, ${}_0D_t^\alpha u = J_0D_t^\alpha v$ and by duality ${}_0D_t^\alpha v(t) = \nabla H(t,u(t))$, therefore ${}_0D_t^\alpha u = J_0D_t^\alpha v = J\nabla H(t,u(t))$, a.e. on $[0,T]$. Moreover, $u(0) = u(T)$ since $u \in X$. The proof is complete.

Lemma 7. *For every $v \in X$, there is*

$$\int_0^T (J_0D_t^\alpha v(t), v(t))\, dt \geq -\tfrac{T^\alpha}{\Gamma(\alpha+1)} \int_0^T \mid {}_0D_t^\alpha v(t) \mid^2 dt.$$

 ISBN: 978-84-617-8694-7

Proof. Let us write $v = \tilde{v} + \bar{v}$, where $\bar{v} = \frac{1}{T}\int_0^T v(s)ds$, then by Cauchy-Schwarz inequality and Lemma 3, we obtain

$$\int_0^T (J_0D_t^\alpha v(t), v(t))\,dt = \int_0^T (J_0D_t^\alpha v(t), \tilde{v}(t))\,dt \geq -\left(\int_0^T \mid J_0D_t^\alpha v(t) \mid^2 dt\right)^{1/2}\left(\int_0^T \mid \tilde{v}(t) \mid^2\right)^{1/2}$$
$$\geq -\frac{T^\alpha}{\Gamma(\alpha+1)}\left(\int_0^T \mid J_0D_t^\alpha v(t) \mid^2 dt\right)^{1/2}\left(\int_0^T \mid_0 D_t^\alpha v(t) \mid^2\right)^{1/2}$$
$$= -\frac{T^\alpha}{\Gamma(\alpha+1)}\int_0^T \mid_0 D_t^\alpha v(t) \mid^2 dt.$$

4 The existence of weak solutions

In this section, the existence theorem of at least one periodic solution to the fractional Hamiltonian systems (2) is proved.

Theorem 1. *Assume that the following conditions are satisfied*

(A1) *there exists* $l \in L^4(0,T;\mathbb{R}^N)$ *such that* $H(t,u) \geq (l(t),u)$ *for all* $u \in \mathbb{R}^{2N}$ *and a.e.* $t \in [0,T]$*;*

(A2) *there exists* $\lambda \in [0, 2\pi/T]$*, and* $\gamma \in L^2(0,T;\mathbb{R}^N)$*, such that for every* $y \in \mathbb{R}^{2N}$ *and a.e.* $t \in [0,T]$ *one has* $H(t,u) \leq \frac{\lambda}{2} \mid u \mid^2 + \gamma(t)$*;*

(A3) $\int_0^T H(t,u)dt \to +\infty$ *as* $\mid u \mid \to \infty, u \in \mathbb{R}^{2N}$*.*

Then the fractional Hamiltonian system (8) *has at least one solution* $u \in Y$ *such that* $v(t) = -J\left[u(t) - \frac{1}{T}\int_0^T u(s)ds\right]$ *minimizes the dual actian* $\chi : X \to [-\infty, +\infty], v \to \int_0^T \left[\frac{1}{2}(J_0D_t^\alpha v(t), v(t)) + H^*(t,{}_0D_t^\alpha v(t))\right]dt$*, that is to say, the fractional Hamiltonian system* (2) *has at least one solution* $x \in E_0^{\alpha,p}$*.*

Proof. We divide the proof into three steps.

Step 1. A perturbed problem is established and existence of a solution of it is proved.

Let $\epsilon_0 > 0$ be such that

$$0 < \epsilon_0 + \lambda < \frac{\Gamma(\alpha+1)}{T^\alpha} \tag{15}$$

and let

$$H_\epsilon : [0,T] \times \mathbb{R}^{2N} \to \mathbb{R}, (t,u) \to \frac{\epsilon \mid u \mid^2}{2} + H(t,u)$$

where $0 < \epsilon < \epsilon_0$. Since the function $F(t,x)$ is measurable on t for every $x \in \mathbb{R}^N$ and continuously differentiable and convex in x for a.e. $t \in [0,T]$, then $H(t,u)$ is measurable on t for all $u \in \mathbb{R}^{2N}$ and continuously differentiable and convex in u for a.e. $t \in [0,T]$. By the defined of H_ϵ, we know that $H_\epsilon(t,\cdot)$ is strictly convex and continuously differentiable for a.e. $t \in [0,T]$ and $H_\epsilon(\cdot,u)$ is measurable on $[0,T]$ for every $u \in \mathbb{R}^{2N}$. From (A1) and (A2), we have

$$-\mid l(u) \mid\mid u \mid + \frac{\epsilon \mid u \mid^2}{2} \leq H_\epsilon(t,u) \leq (\lambda+\epsilon_0)\frac{\mid u \mid^2}{2} + \gamma(t),$$

 ISBN: 978-84-617-8694-7

therefore

$$\frac{\epsilon \mid u \mid^2}{4} - \frac{\mid l(t) \mid^2}{2} \leq H_\epsilon(t,u) \leq (\lambda+\epsilon_0)\frac{\mid u \mid^2}{2} + \gamma(t), \tag{16}$$

So, by Lemma 6, the perturbed dual action

$$\chi_\epsilon(v) = \int_0^T \left[\frac{1}{2}(J_0 D_t^\alpha v(t), v(t)) + H_\epsilon^*(t, {}_0D_t^\alpha v(t))\right] dt$$

is continuously differentiable on $\tilde{X}$ and if $v_\epsilon \in \tilde{X}$ is a critical point of χ_ϵ, the function u_ϵ defined by

$$u_\epsilon(t) = \nabla H_\epsilon^*(t, {}_0D_t^\alpha v(t))$$

is a solution of

$$\begin{cases} J_0 D_t^\alpha u(t) + \epsilon u(t) + \nabla H(t,u) = 0, \\ u(0) = u(T), \end{cases} \tag{17}$$

and the relation $J_0 D_t^\alpha v_\epsilon =_0 D_t^\alpha u_\epsilon$ holds.

By (16) and Propositions 2.2 in [14], we have

$$H_\epsilon^*(t, {}_0D_t^\alpha v(t)) \geq \frac{1}{2}\left(\frac{1}{\lambda+\epsilon_0}\right) \mid_0 D_t^\alpha v(t) \mid^2 -\gamma(t),$$

which together with Lemma 7 implies that

$$\begin{aligned} \chi_\epsilon(v) &\geq \frac{1}{2}\left(\frac{1}{\lambda+\epsilon_0} - \frac{\Gamma(\alpha+1)}{T^\alpha}\right)\int_0^T \mid_0 D_t^\alpha v(t) \mid^2 dt - \int_0^T \gamma(t)dt \\ &= \delta_0 \parallel_0 D_t^\alpha v(t) \parallel_{L^2}^2 -\gamma_0, \end{aligned} \tag{18}$$

where $\delta_0 = \frac{1}{2}\left(\frac{1}{\lambda+\epsilon_0} - \frac{\Gamma(\alpha+1)}{T^\alpha}\right) > 0$ by (15) and $\gamma_0 = \int_0^T \gamma(t)dt$.

Let $\{v_k\}$ be a minimizing sequence for χ_ϵ. It follows from (18)that $\{\parallel_0 D_t^\alpha v_k(t) \parallel_{L^2}\}$ is bounded, then Lemma 3 implies that $\{v_k\}$ is bounded in $\tilde{X}$. Now we show χ_ϵ is weakly lower semi-continuous (w.l.s.c.) on $\tilde{X}$. From the continuity of H_ϵ and the definition of H_ϵ^*, it follows that $\chi_{\epsilon,1}(v) = \int_0^T H_\epsilon^*(t, {}_0D_t^\alpha v(t))dt$ is w.l.s.c. on $\tilde{X}$ and $\chi_{\epsilon,2}(v) = \frac{1}{2}\int_0^T (J_0 D_t^\alpha v(t), v(t))dt$ is w.l.s.c. on $\tilde{X}$. Thus $\chi_\epsilon = \chi_{\epsilon,1}(v) + \chi_{\epsilon,2}(v)$ is w.l.s.c. on $\tilde{X}$ and by Lemma 5, has a minimum at some point $v_\epsilon \in \tilde{X}$.

Step 2. A posteriori estimates on u_ϵ

By assumption (A1), (A2) and Proposition 2.2, we have

$$\mid \nabla H(t,u) \mid \leq 2(\lambda+1)\left[\mid u \mid + \frac{|l(t)|^2}{2} + \gamma(t)\right] + 1 + \mid u \mid .$$

It is then easy to verify that the function $\bar{H} : \mathbb{R}^{2N} \to \mathbb{R}, u \to \int_0^T H(t,u)dt$ is continuously differentiable. By assumption (A3), $\bar{H}$ has a minimum at some point $u \in \mathbb{R}^{2N}$ for which $\int_0^T \nabla H(t,\bar{u})dt = 0$, so that the problem

$${}_0D_t^\alpha v(t) = \nabla H(t,\bar{u}) \tag{19}$$

 ISBN: 978-84-617-8694-7

has a unique solution $\eta \in \tilde{X}$ such that $\int_0^T \eta(s)ds = 0$. By (19), $H^*(t,{}_0D_t^\alpha\eta(t)) = ({}_0D_t^\alpha\eta(t),\bar{u}) - H(t,\bar{u})$ so that $H^*(\cdot,{}_0D_t^\alpha\eta(\cdot)) \in L^1(0,T;\mathbb{R})$. From the inequality $H(t,u) \le H_\epsilon(t,u)$ we deduce $H_\epsilon^*(t,v) \le H^*(t,v)$ and from (18), we obtain

$$\begin{aligned}&\delta_0 \parallel {}_0D_t^\alpha v(t) \parallel_{L^2}^2 - \gamma_0 \le \chi_\epsilon(v_\epsilon) \le \chi_\epsilon(\eta)\\ &\le \int_0^T \left[\tfrac{1}{2}(J_0D_t^\alpha\eta(t),\eta(t)) + H_\epsilon^*(t,{}_0D_t^\alpha\eta(t))\right]dt = c_1 < \infty.\end{aligned}$$

Therefore $\parallel {}_0D_t^\alpha v_\epsilon \parallel_{L^2} \le c_2$. According to $J_0D_t^\alpha v_\epsilon = {}_0D_t^\alpha u_\epsilon$, we have $\parallel {}_0D_t^\alpha \tilde{u}_\epsilon \parallel_{L^2} = \parallel {}_0D_t^\alpha u_\epsilon \parallel_{L^2} \le c_2$, where $\tilde{u}_\epsilon = u_\epsilon - \bar{u}_\epsilon, \bar{u}_\epsilon = \frac{1}{T}\int_0^T u_\epsilon(t)dt$. Lemma 3 implies that $\parallel \tilde{u}_\epsilon \parallel \le c_3$. The convexity of $H(t,\cdot)$ and (17) reduce to

$$\begin{aligned}&H\left(t,\tfrac{\bar{u}_\epsilon(t)}{2}\right) = H\left(t,\tfrac{u_\epsilon(t)}{2} - \tfrac{\tilde{u}_\epsilon(t)}{2}\right) \le \tfrac{1}{2}H(t,u_\epsilon(t)) + \tfrac{1}{2}H(t,-\tilde{u}_\epsilon(t))\\ &\le \tfrac{1}{2}(\nabla H(t,u_\epsilon(t)),u_\epsilon(t)) + \tfrac{1}{2}H(t,0) + \tfrac{\lambda}{4} \mid \tilde{u}_\epsilon(t) \mid^2 + \tfrac{\gamma(t)}{2}\\ &\le \tfrac{1}{2}(-J_0D_t^\alpha u_\epsilon(t),u_\epsilon(t)) - \tfrac{\epsilon}{2} \mid u_\epsilon(t) \mid^2 + \tfrac{\lambda}{4} \mid \tilde{u}_\epsilon(t) \mid^2 + \tfrac{\gamma(t)}{2}.\end{aligned}$$

Using Lemma 7, we obtain

$$\begin{aligned}&\int_0^T H(t,\bar{u}_\epsilon(t))dt \le -\tfrac{1}{2}\int_0^T (J_0D_t^\alpha u_\epsilon(t),u_\epsilon(t)) + \tfrac{\lambda}{4} \parallel \tilde{u}_\epsilon(t) \parallel_{L^2}^2 + \gamma_0\\ &\le \tfrac{T^\alpha}{2\Gamma(\alpha+1)} \parallel {}_0D_t^\alpha\tilde{u}_\epsilon(t) \parallel_{L^2}^2 + \tfrac{\lambda}{4} \parallel \tilde{u}_\epsilon(t) \parallel_{L^2}^2 + \gamma_0\\ &\le \tfrac{T^\alpha}{2\Gamma(\alpha+1)}c_2^2 + \tfrac{\lambda}{4}c_3^2 + \gamma_0 = c_4.\end{aligned}$$

By assumption (A3), $\mid \bar{u}_\epsilon \mid \le c_5$, we have $\parallel u_\epsilon \parallel \le \parallel \tilde{u}_\epsilon \parallel + \parallel \bar{u}_\epsilon \parallel \le c_3 + \sqrt{T}c_5 = c_6$.

Step 3. Existence of a solution for the original problem.

From $\parallel u_\epsilon \parallel \le c_6$, there exists a sequence $\{\epsilon_n\}$ tending to 0 in $[0,\epsilon_0]$ and some $u \in Y$ such that u_{ϵ_n} converge weakly to u in Y. Moreover, as ${}_0D_t^\alpha v_\epsilon = -J_0D_t^\alpha u_\epsilon$, we have $v_\epsilon(t) = -J(u_\epsilon(t) - \bar{u}_\epsilon)$. so that v_{ϵ_n} converges weakly to

$$v(t) = -J(u - \bar{u}). \tag{20}$$

By Proposition 1.2 in [14], u_{ϵ_n} (resp. v_{ϵ_n}) converges uniformly to u (resp. v) on $[0,T]$. From (17) in integrated form

$$Ju_{\epsilon_n}(t) - Ju_{\epsilon_n}(0) + \int_0^T \left[\epsilon_n u_{\epsilon_n}(s) + \nabla H(s,u_{\epsilon_n}(s))\right]ds = 0,$$

it follows that

$$Ju(t) - Ju(0) + \int_0^T \nabla H(s,u(s))ds = 0,$$

therefore $u \in Y$ is a solution of (8).

Finally, we will show that $v = (v_1,v_2)$ minimizes the dual action χ. since

$$H_\epsilon^*(t,v) \le H^*(t,v) \text{ for all } h \in X,$$

 ISBN: 978-84-617-8694-7

we have

$$\chi_{\epsilon_n}(v_{\epsilon_n}) \leq \chi_{\epsilon}(h) \leq \chi(h).$$

Now by the definition $H^*(t,\cdot)$ and duality between u_{ϵ_n} and ${}_0D_t^{\alpha}v_{\epsilon_n}$, we obtain

$$\begin{aligned}\chi_{\epsilon_n}(v_{\epsilon_n}) &= \int_0^T \left[\tfrac{1}{2}(J_0D_t^{\alpha}v_{\epsilon_n}(t), v_{\epsilon_n}(t)) + (u_{\epsilon_n},{}_0D_t^{\alpha}v_{\epsilon_n}(t)) - H_{\epsilon_n}(t,u_{\epsilon_n}(t))\right]dt\\ &= \int_0^T \left[\tfrac{1}{2}(J_0D_t^{\alpha}v_{\epsilon_n}(t), v_{\epsilon_n}(t)) + (u_{\epsilon_n},{}_0D_t^{\alpha}v_{\epsilon_n}(t)) - H(t,u_{\epsilon_n}(t)) - \tfrac{\epsilon_n}{2} \mid u_{\epsilon_n}(t) \mid^2\right]dt.\end{aligned}$$

It follows from (8) and (20) that

$${}_0D_t^{\alpha}v(t) = \nabla H(t,u(t)) \qquad \text{a.e. on } [0,T]. \tag{21}$$

Letting $t \to \infty$ in (21), we have, by (21)

$$\begin{aligned}\lim_{n\to\infty}\chi_{\epsilon_n}(v_{\epsilon_n}) &= \int_0^T \left[\tfrac{1}{2}(J_0D_t^{\alpha}v(t), v(t)) + (u(t),{}_0D_t^{\alpha}v(t)) - H(t,u(t))\right]dt\\ &= \int_0^T \left[\tfrac{1}{2}(J_0D_t^{\alpha}v(t), v(t)) + H^*(t,{}_0D_t^{\alpha}v(t))\right]dt = \chi(v).\end{aligned}$$

Thus $\chi(v) \leq \chi(h)$ for all $h \in X$. The proof is completed.

When $H(t,\cdot)$ is strictly convex, we deduce from Theorem 1 that there exists a necessary and sufficient condition for the solvability of the fractional Hamiltonian systems (2)

Corollary 1. *Assume that $H(t,\cdot)$ is strictly convex for a.e. $t \in [0,T]$ and satisfies the conditions* (A1) *and* (A2) *of Theorem* 1. *Then the following conditions are equivalent.*

(A4) *Problem* (8) *is solvable, i.e. problem* (2) *is solvable.*

(A5) *There exists $\bar{x} \in \mathbb{R}^{2N}$ such that $\int_0^T \nabla H(t,\bar{x})dt = 0$.*

(A6) $\int_0^T H(t,x)dt \to +\infty$ *when* $\mid x \mid \to \infty$.

Abstract

In this work, we concern to develop a new with memory method for solving nonlinear equations. To this end, we use three functional evaluation per iteration. In addition, our method is constructed by the information of Hermite's interpolation. It has convergence order 5.5. Some numerical examples are included to show the efficiency and its applicability.

Key words: With memory method, Hermit's interpolation, efficiency, accuracy, convergence order.

1 Introduction

There are so many problems in science and technology that lead to nonlinear of equations. Solving these equation is based on iterative methods. However, such methods should satisfy some standards, Kung and Traub [2], and Ostrowski [1] proposed two criteria for this purpose: optimality and efficiency.
Kung and Traub established that any two-step without memory method is optimal and uses three functional evaluations having convergence order four. Also, efficiency index is defined by $E(p,n) = p^{1/n}$, where p and n are convergence order and functional evaluations, respectively. Therefore any two- step without memory method has the same efficiency index $E(4,3) = 4^{1/3} \simeq 1.587$ [2]. Following Traub's idea of introducing with memory methods, many researcher [2] constructed many with memory methods [3]. Most of these methods are

 ISBN: 978-84-617-8694-7

free derivative [4], [5] and [6]. To the best of our knowledge, construction of with memory method in which they use derivative, are few.

It is well-known that iterative method for solving nonlinear equation is divided into two general categories with and without memory. There has been many attempts to construct optimal without memory methods of both kinds them [6]. Traub in his book shows that it is possible to increase the convergence order of Steffensen type method without any new functional evaluation. His idea has been followed by many authors. On the other hand, there are few methods of such kind [7] that use derivatives. Hence, in this work we focus on developing new kind of such methods, say, a new with memory method based on Hermite's interpolation.

The rest of this work is organised as follows: In Section 2, we design an optimal without memory method. Then we attempt to derive two kinds of with memory methods. In Section 3, some numerical examples are presented. Section 4 concludes this work.

2 The method and analysis of convergence

Consider the following two-step method

$$\begin{cases} y_n = x_n - \frac{f(x_n)}{f'(x_n)}, \\ x_{n+1} = y_n - \frac{f(y_n)}{f'(y_n)}, \qquad n = 0, 1, 2, \ldots. \end{cases} \tag{2.1}$$

when x_0 is given. This method is not optimal. We approximate $f'(y_n)$ in the second step by Hermite's interpolation.

Let

$$P(t) = f(y_n) + (t - y_n)f[y_n, x_n] + (t - y_n)(t - x_n)f[y_n, x_n, x_n]$$

where

$$f[x_n, x_n] = f'(x_n), f[x_n, y_n] = \frac{f(x_n) - f(y_n)}{x_n - y_n}$$

and

$$f[y_n, x_n, x_n] = \frac{f[y_n, x_n] - f[x_n, x_n]}{y_n - x_n}.$$

Therefore,

$$p'(t) = f[y_n, x_n] + (2t - y_n - x_n)f[y_n, x_n, x_n],$$

Hence

$$f'(y_n) \simeq p'(y_n) = f[y_n, x_n] + (y_n - x_n)f[y_n, x_n, x_n]$$

 ISBN: 978-84-617-8694-7

Consequently,

$$\begin{cases} y_n = x_n - \dfrac{f(x_n)}{f'(x_n)}, \\ x_{n+1} = y_n - \dfrac{f(y_n)}{f[y_n, x_n] + (y_n - x_n) f[y_n, x_n, x_n]}, \qquad n = 0, 1, 2, \ldots. \end{cases} \tag{2.2}$$

This method is optimal and has convergence order four.

Theorem 2.1. *Method (2.2) has convergence order four if x_0 is close enough to the sough zero. It's error equation is $e_{n+1} = (c_2^2 - c_2 c_3) e_n^4 + o(e_n^5)$*

Now, we modify Method (2.2) to as follows:

$$\begin{cases} y_n = x_n - \dfrac{f(x_n)}{f'(x_n) + \alpha_n f(x_n)}, \\ x_{n+1} = y_n - \dfrac{f(y_n)}{f[y_n, x_n] + (y_n - x_n) f[y_n, x_n, x_n]}, \qquad n = 0, 1, 2, \ldots. \end{cases} \tag{2.3}$$

Theorem 2.2. *The error equation of method (2.3)is given by $e_{n+1} = (\alpha_n + c_2)(c_2(\alpha_n + c_2) - c_3) e_n^4 + o(e_n^5)$*

To derive a with memory method, we use suppose $\alpha_n + c_n = 0$, or $\alpha_n = -c_2 = -\frac{f''(\alpha)}{2f'(\alpha)}$. Since α is unknown,we use $f''(\alpha) \simeq p''(y_n) = 2f[y_n, x_n, y_n]$ and $f'(\alpha) \simeq p'(y_n)$.
If in each iteration, we use the following accelerator $\alpha_n = -\dfrac{p''(y_n)}{2p(y_n)}$, then we have

Theorem 2.3. *If $\alpha_n = -\dfrac{p''(y_n)}{2p(y_n)}$, then convergence order of method (2.3) is 5.*

It is still possible to increase the convergence order. Consider the following modification of (2.3)

$$\begin{cases} y_n = x_n - \dfrac{f(x_n)}{f'(x_n) + \alpha_n f(x_n)}, \\ x_{n+1} = y_n - \dfrac{f(y_n)}{f[e, e_y] + (e_y - e) f[e_y, e, e] + \beta_n (e_y - e)^2}, \qquad n = 0, 1, 2, \ldots. \end{cases} \tag{2.4}$$

We have the following error equation

 ISBN: 978-84-617-8694-7

Theorem 2.4. *The error equation of method (2.4) is given by*

$$e_{n+1} = \frac{1}{f'(\alpha)}(c_2+\alpha_n)\Big(\beta_n + f'(\alpha)c_2(\alpha_n+c_2) - f'(\alpha)c_3\Big)e_n^4 + o(e_n^5)$$

If $\alpha + c_2 = 0$, then we can set $\beta_n = \dfrac{f'''(\alpha)}{6}$.
Here if is still possible to approximate the accelerator β_n by the interpolatory

$$N_3(t, y_n, y_{n-1}, x_{n-1}, x_{n-1}),$$

where

$$\begin{aligned} N_3(t) =& f(y_n) + (y_n - t)f[y_n, x_n] \\ &+(t-y_n)(t-x_n)f[y_n, x_{n-1}, x_{n-1}] \\ &+(t-y_n)(t-x_{n-1})f[y_n, x_{n-1}, x_{n-1}, y_{n-1}] \end{aligned}$$

Hence,

Theorem 2.5. *If* $\alpha_n = -\dfrac{p''(y_n)}{2p'(y_n)}$ *and* $\beta_n = \dfrac{N_3'''(y_n)}{6}$, *then method (2.4) has convergence order* 5.5.

Methods (2.3), (2.4) are called with memory method since they use information from the current and the previous iterations. To the best our knowledge, method (2.4) is the first method of its kind. Indeed previous works have increased the convergence order at most to five.

3 Numerical results and comparisons

In this section, the family of with memory methods

$$\begin{cases} y_n = x_n - \dfrac{f(x_n)}{\lambda_n f(x_n) + f'(x_n)}, \\ x_{k+1} = y_n - \dfrac{f(y_n)}{2\lambda_n f(x_n) + f'(x_n)}\Big(1 + 2\dfrac{f(y_n)}{f(x_n} + \tau(\dfrac{f(y_n)}{f(x_n)})^2\Big), \end{cases} \tag{3.1}$$

$$\begin{cases} y_n = x_n - \dfrac{f(x_n)}{\lambda_n f(x_n) + f'(x_n)}, \\ x_{n+1} = y_n - \dfrac{f(y_n)}{2\lambda_n f(x_n) + f'(x_n)}\Big(\dfrac{f(x_n) + (2+\beta)f(y_n)}{f(x_n) + \beta f(y_n)}\Big) \end{cases} \tag{3.2}$$

 ISBN: 978-84-617-8694-7

methods	$\lvert x_1-\alpha\rvert$	$\lvert x_2-\alpha\rvert$	$\lvert x_3-\alpha\rvert$	r_c
Method (3.1)	0.5505(-1)	0.7972(-5)	01081(-24)	4.99
Method (3.2)	0.5505(-1)	07972(-5)	0.4138(-24)	4.99
Our Method(2.3)	0.8524(-1)	0.8780(-4)	0.1952(-19)	5.0
Our Method(2.4)	0.9195(-1)	0.5435(-4)	0.3306(-23)	5.5

Table 1: $f(x)=\dfrac{1}{t^4}-t^2-\dfrac{1}{t}+1,\ x_0=1,\ \alpha=2,\ \lambda=-0.01$

where $\lambda_n=-c_2=-\dfrac{f''(\alpha)}{2f'(\alpha)}$

These tables include the values of the computational order of convergence r_c calculated by the formula [3]

$$r_c=\frac{\log\lvert f(x_n)/f(x_{n-1})\rvert}{\log\lvert f(x_{n-1})/f(x_{n-2})\rvert}. \tag{3.3}$$

Table 1 shows that the Method (2.4) competes the previous methods. In additional its efficiency index is better than the previous works. In other words, it has efficiency index $5.5^{\frac{1}{3}}\simeq 1.76$ greater than $5^{\frac{1}{3}}\simeq 1.70$.

4 Conclusion

In this work, we developed a new kind of with memory methods for solving nonlinear equations. To this end, based on Hermite's interpolation, two special kinds, of the methods were derived. One of them increases the convergence order from 4 to 5, and the other one from 4 to 5.5. The latter kind has not been studied yet in the literature and can compete with every current with memory in its class. This method is under developing for general case.

Abstract

In this paper, we propose a family of optimal eighth order convergent iterative methods for multiple roots with known multiplicity with the introduction of two free parameters and three univariate weight functions. Also numerical experiments have been applied to a number of test equations for a special scheme from this family that satisfies the conditions given in this paper.

Key words: Nonlinear equations, Optimal iterative methods, Multiple root
MSC 2000: 65H05, 65H10

1 Introduction

Newton's method for multiple roots is quadratically convergent for every root. It determines simple or multiple zeros of a non-linear equation. If the given function has only a simple zero, then Newton's method converges quadratically to the exact solution. In past, it was very difficult to construct a higher-order optimal multi-point scheme for multiple zeros of the given function with multiplicity $m \geq 1$. Nowadays, with the digital computer, advanced computer arithmetics, software and symbolic computation, the construction of higher-order optimal multi-point methods has become easier. Many researchers presented optimal fourth-order iterative methods for multiple zeroes like Li et al. [7] in 2009, Sharma and Sharma [9] in 2010, Sharifi et al.[8] in 2012, Liu and Zhou [6] and Zhou et al.[12] in 2013, Thukral [11] in 2014, Hueso et al.[5] in 2015 and Behl et al. [1] in 2016. In recent years, at most

 ISBN: 978-84-617-8694-7

sixth-order convergence method has been given for finding multiple zeros that can be found in the available literature. There are only three multi-point iterative schemes with sixth-order convergence for multiple zeros. First one was proposed by Thukral [11] and other two were presented by Geum et al.[3]. In 2013, Thukral [10] presented a multi-point iterative method with sixth-order convergence, which is given by

$$y_n = x_n - m\frac{f(x_n)}{f'(x_n)}, \tag{1}$$

$$z_n = x_n - m\frac{f(x_n)}{f'(x_n)}\sum_{i=1}^{3}\left(\frac{f(y_n)}{f(x_n)}\right)^{\frac{i}{m}}, \tag{2}$$

$$x_{n+1} = z_n - m\frac{f(x_n)}{f'(x_n)}\left(\frac{f(z_n)}{f(x_n)}\right)^{\frac{1}{m}}\left[\sum_{i=1}^{3}\left(\frac{f(y_n)}{f(x_n)}\right)^{\frac{i}{m}}\right]^2. \tag{3}$$

In 2015, Geum et al.[3], have given the following two-point sixth-order iterative scheme:

$$y_n = x_n - m\frac{f(x_n)}{f'(x_n)}, m > 1, \tag{4}$$

$$x_{n+1} = x_n - Q(p_n, s_n)\frac{f(x_n)}{f'(x_n)}, \tag{5}$$

where $p_n = \sqrt[m]{\frac{f(y_n)}{f(x_n)}}$, $s_n = \sqrt[m-1]{\frac{f'(y_n)}{f'(x_n)}}$ and $Q : C^2 \to C$ is holomorphic function in the neighborhood of origin (0,0). In 2016, Geum et al. [4], have again proposed a three-point iterative scheme with sixth-order convergence for multiple zeros. The proposed scheme was based on weight functions, which can be seen in the following expression:

$$y_n = x_n - m\frac{f(x_n)}{f'(x_n)}, m > 1, \tag{6}$$

$$w_n = x_n - mG(p_n)\frac{f(x_n)}{f'(x_n)}, \tag{7}$$

$$x_{n+1} = x_n - mK(p_n, t_n)\frac{f(x_n)}{f'(x_n)}, \tag{8}$$

where $p_n = \sqrt[m]{\frac{f(y_n)}{f(x_n)}}$, $t_n = \sqrt[m]{\frac{f(w_n)}{f(x_n)}}$ and $G : C \to C$ is analytic in a neighborhood of 0 and $K : C^2 \to C$ is holomorphic in the neighborhood of (0,0). All of the above three schemes (1)-(6) require four function evaluations in order to produce sixth-order convergence. The iterative method (4) has one drawback that it does not work for simple zeros (i.e. for $m = 1$). Moreover, there does not exist any optimal scheme greater than fourth-order convergence. So, we propose an optimal eighth-order convergent iterative method for multiple root of a nonlinear equation. The main reason of this proposed method is to present a new higher-order optimal scheme for finding simple as well as multiple zeros of nonlinear equations.

 ISBN: 978-84-617-8694-7

The rest of the paper is organized as follows: In Section 2, we propose a new family of optimal eighth-order iterative methods to find multiple roots of nonlinear equation and discuss its convergence analysis, defining an special case whose performance will be checked in Section 4, in comparison with some existing sixth-order ones. Concluding remarks are given in Section 5.

2 Construction of the Scheme

This section is devoted to the construction and convergence analysis of this proposed scheme with the main theorem. So, we propose a new eighth-order scheme for a known multiplicity $m \geq 1$ of the desired multiple zero as follows

$$\begin{aligned} y_n &= x_n - m\frac{f(x_n)}{f'(x_n)}, \\ z_n &= x_n - mu_nH(u_n)\frac{f(x_n)}{f'(x_n)}, \\ x_{n+1} &= x_n - u_nv_n(A_2 + A_3u_n)P(v_n)G(w_n)\frac{f(x_n)}{f'(x_n)}, \end{aligned} \tag{9}$$

where $A_2, A_3 \in R$ are three free parameters and the weight functions $H : \mathbb{C} \to \mathbb{C}$, $P : \mathbb{C} \to \mathbb{C}, /G : \mathbb{C} \to \mathbb{C}$ are analytic function in the neighborhood of 0 with

$$u_n = \left(\frac{f(y_n)}{f(x_n)}\right)^{\frac{1}{m}}, \quad v_n = \left(\frac{f(z_n)}{f(y_n)}\right)^{\frac{1}{m}}, \quad w_n = \left(\frac{f(z_n)}{f(x_n)}\right)^{\frac{1}{m}},$$

are the variables of the weight functions. It is worthy to note that we will obtain well known King's family of fourth-order iterative methods for $m = 1$ with the help of first two substeps. In the next Theorem 1, we demonstrate that the order of convergence of the proposed scheme will reach at optimal eight without using additional functional evaluations.

Theorem 1 *Let us consider $x = \alpha$(say) be a multiple zero with a multiplicity $m \geq 1$ of the involved function f. In addition we assume that $f : \mathbb{C} \to \mathbb{C}$ be an analytic function in the region enclosing a multiple zero α. The proposed scheme defined by (9) has an optimal eighth-order convergence, when it satisfies the following expressions:*

$$\begin{aligned} A_2 &= 1, A_3 = 2A_2, \\ H_0 &= H(0) = 1, H_1 = H'(0) = 2, H_2 = H''(0) = -2, H_3 = H'''(0) = 36, \\ P_0 &= P(0) = P'(0), G_0 = G(0) = \frac{m}{P_0A_2}, G_1 = G'(0) = \frac{2m}{P_0A_2} \end{aligned}$$

 ISBN: 978-84-617-8694-7

and the error equation is given as:

$$\begin{aligned} e_{n+1} &= \frac{1}{48m^7P_0}c_1c_1^2(11+m)-2mc_2)((14(59+12m+m^2)P_0-3\,(11+m)^2\,P_2)c_1^4 \\ &\quad -12m(4(7+m)P_0-(11+m))c_1^2c_2+12m^2\,(2P_0-P_2)\,c_2^2+24m^2P_0c_1c_3)e_n^8 \\ &\quad +O(e_n^9). \end{aligned}$$

Now, we define an special case of our proposed scheme that will be used in the numerical section. Let us describe the following polynomial weight function directly from the proposed Theorem 1:

$$H(u)=6u^3-u^2+2u+1,\ P(v)=v+1,\ G(w)=\frac{2mw}{A_2P_0}+\frac{m}{A_2P_0} \tag{10}$$

for

$$u_n=\left(\frac{f(y_n)}{f(x_n)}\right)^{\frac{1}{m}},\ v_n=\left(\frac{f(z_n)}{f(y_n)}\right)^{\frac{1}{m}},\ w_n=\left(\frac{f(z_n)}{f(x_n)}\right)^{\frac{1}{m}}.$$

Thus, the corresponding optimal eighth-order iterative scheme is given by

$$y_n = x_n-m\frac{f(x_n)}{f'(x_n)}, \tag{11}$$

$$z_n = y_n-mu(6u^3-u^2+2u+1)\frac{f(x_n)}{f'(x_n)}, \tag{12}$$

$$x_{n+1} = z_n-muv(1+2u)(v+1)(2w+1)\frac{f(x_n)}{f'(x_n)}. \tag{13}$$

In what follows, it will be denoted by M1.

3 Numerical experiments

This section is devoted to demonstrate the efficiency, effectiveness and convergence behavior of the presented schemes. In this regard, we consider the proposed scheme M1 and choose four test problems for comparison given in the Examples 1-4. Now, we want to compare our methods with other existing methods of same domain on the basis of error per iteration and computational order of convergence COC. We have chosen sixth-order iterative methods for the comparison which is the highest-order till date for multiple zeros. Therefore, we compare the proposed methods with the family of two-point sixth-order methods, which were presented by Geum et al. in [4], out of them we consider (4) and (6) denoted by GM1 and GM2 respectively for $Q(p_n,s_n)=m(1+2(m-1)(p_n-s_n)-4p_ns_n+s_n^2),\ G(p_n)=1+p_n+2p_n^2$, and $K\,(p_n,t_n)=1+p_n+2p_n^2+(1+2p_n)t_n$.

We did our calculations with several number of significant digits (minimum 1000 significant digits) to minimize the round off error. We calculate the values of all the constants

 ISBN: 978-84-617-8694-7

$f_1(x), x_0 = -0.92, m = 4$				
$\lvert x_n - \alpha\rvert$	$\lvert x_1 - \alpha\rvert$	$\lvert x_2 - \alpha\rvert$	$\lvert x_3 - \alpha\rvert$	p_n
$GM1$	2.595063462(-8)	8.177972395(-47)	8.009985192(-278)	5.999999996
$GM2$	7.630978643(-8)	1.380544256(-43)	4.840288751(-258)	5.999999989
$M1$	5.980551468(-10)	2.106002934(-74)	4.979673785(-590)	7.999999999

Table 1: Numerical results on $f_1(x)$

and functional residuals up to several number of significant digits but due to the limitations, we display the value of errors per iterations and absolute residual errors in the function up to 9 decimal digits with exponent power in Tables 1–4.

Also we calculate the computational order of convergence,

$$p_n \approx \frac{\log|(x_{k+1} - \alpha)/(x_k - \alpha)|}{\log|(x_k - \alpha)/(x_{k-1} - \alpha)|},$$

due to Weerakoon and Fernando, in order to check the theoretical order of convergence.

Example 1 *Let us consider the following standard nonlinear test function from Geum et al. [3]*

$$f_1(x) = [cos(\frac{\pi x}{2}) + e^{1-x^2} - x - 2]^4. \tag{14}$$

The above function has a multiple zero at $\alpha = -1$ of multiplicity 4 with initial guess -0.92, which has been used to test the methods. The obtained results have been presented in Table 1, where theoretical order of convergence is reached and the higher order of convergence is observed in better precision of the results per iteration.

In order to check if this initial estimation is representative enough to show the performance of these methods, we present in Figure 4 the dynamical plane corresponding to each one of the methods applied on $f_1(x)$ with a mesh of 401×401 complex initial estimations. When the method is used with one of these initial guesses and it converges to one of the zeros of the nonlinear function in less than 80 iterations, it is plotted in the color assigned to the root. If it has not converged in 80 iterations, then this point is plotted in black. The programs used to make this figure appears in [2].

It is observed that the behavior is good in all the methods. The order makes the differences in two senses: the convergence, if exists, is quicker in M1 but, as it is usual, the set of convergent initial estimations decreases as the order increases.

Example 2 *We assume another standard test problem.*

$$f_2(x) = [cos(\frac{\pi x}{2}) + x^2 - \pi]^5. \tag{15}$$

4 Conclusion

We have proposed an optimal eighth-order family of iterative methods for solving nonlinear equations for multiple roots with known multiplicity. The family of methods include two free parameters and three weight functions involving function-to-function ratio. The methods involve only one derivative evaluation. Moreover, numeric and graphical tests show that the proposed method has good performance as compared with other similar methods.

Robust a posteriori error estimation for a weak Galerkin finite element discretization of Stokes equations

Xiaobo Zheng and Xiaoping Xie

School of Mathematics, Sichuan University, Chengdu 610064, China

emails: zhengxiaobosc@yahoo.com, xpxie@scu.edu.cn

Abstract

This paper proposes a robust residual-based a posteriori error estimator for a weak Galerkin finite element method for the Stokes equations in two and three dimensions. The estimator consists of two terms. The first term characterizes the difference between the L^2-projection of the velocity approximation on the element interfaces and the corresponding numerical trace, and the second term is related to the jump of the velocity approximation between the adjacent elements. We show that the estimator is reliable and efficient through two estimates of global upper and global lower bounds, up to two data oscillation terms caused by the source term and the nonhomogeneous Dirichlet boundary condition. The estimator is also robust in the sense that the constant factors in the upper and lower bounds are independent of the viscosity coefficient. Numerical results are provided to verify the theoretical results.

Key words: the Stokes equations, weak Galerkin method, a posteriori error estimator.

1 Introduction

Let $\Omega \subset \mathbb{R}^d$ $(d = 2, 3)$ be a bounded polygonal or polyhedral domain. We consider the following Stokes problem: find the velocity $\boldsymbol{u}$ and the pressure p such that

$$\begin{aligned} -\nu\Delta\boldsymbol{u} + \nabla p &= \boldsymbol{f}, && \text{in } \Omega, \\ \nabla \cdot \boldsymbol{u} &= 0, && \text{in } \Omega, \\ \boldsymbol{u} &= \boldsymbol{g}, && \text{on } \partial\Omega. \end{aligned} \tag{1.1}$$

ISBN: 978-84-617-8694-7

where $\nu > 0$ denotes the viscosity coefficient, $\boldsymbol{f} \in [L^2(\Omega)]^d$ is the body force, and $\boldsymbol{g}$ satisfies the compatibility condition $\int_{\partial\Omega} \boldsymbol{g} \cdot \boldsymbol{n} = 0$, with $\boldsymbol{n}$ being the unit outward vector normal to the boundary $\partial\Omega$.

The development of reliable and efficient a posteriori error estimators for finite element discretizations of the Stokes problem has become an active research area over the last several decades (see, e.g. [17, 1, 2, 18, 8, 4, 13, 10, 3, 15, 9, 11, 7], and the references therein). In [17], two a posteriori error estimators were presented for the mini-element based on the residual of the finite element solution and on the solution of local problems. Some related results can be found in [1, 2]. A posteriori error estimators were analyzed for non-conforming finite element approximations in [18, 8, 9], for discontinuous Galerkin methods in [13, 15], and for dual mixed finite element methods in [10, 3]. In [11] a unified framework for a posteriori error estimation for the Stokes problem was developed based on H^1-conforming velocity reconstruction and H(div)-conforming, locally conservative flux (stress) reconstruction. We also refer to [4, 7] for a posteriori error analysis for quasi-Newtonian fluid flows.

In [20] a weak Galerkin(WG) finite element method was presented for the Stokes equations (1.1) in the primary velocity-pressure formulation. The method uses P_k/P_{k-1} $(k \geq 1)$ discontinuous finite element combination for the velocity and pressure, with the velocity element being enhanced by polynomials of degree $k-1$ on the interface of the finite element partition. The usual gradient and divergence operators are implemented as distributions in properly-defined spaces. Optimal-order error estimates were established for the corresponding numerical approximation in various norms. We refer to [5, 21] for another two classes of WG methods for (1.1) and to [22] for a divergence-free WG method for the quasi-Newtonian Stokes flows. We note that in [6] the first a posteriori error analysis of WG methods was carried out for diffusion equations, where the residual type a posteriori error estimator is a combination of the standard conforming Galerkin finite elements and mixed finite elements.

In this paper, we develop a residual type a posteriori error estimator for the WG method in [20] for the Stokes problem (1.1) in two and three dimensions. The a posteriori error estimator for the velocity error plus the pressure error consists of two terms. The first term characterizes the difference between the L^2-projection of the velocity approximation on the element interfaces and the corresponding numerical trace, and the second term is related to the jump of the velocity approximation between the adjacent elements. We show that the estimator is reliable and efficient with two estimates of global upper and global lower bounds, up to two data oscillation terms caused by the source term and the nonhomogeneous Dirichlet boundary condition. We note that the a posteriori estimation is robust with respect to the viscosity coefficient. The main tool of our analysis is the Helmholtz decomposition for tensor fields.

The rest of the paper is organized as follows. Section 2 introduces notations and the WG scheme of [20]. Section 3 describes the a posteriori error estimator and proves its reliability and efficiency. Finally, Section 4 gives some numerical experiments.

An Approximation Algorithm for the BWC Problem

Shira Zucker[1]

[1] *Department of Computer Sciences, Sapir Academic College, Shaar Hanegev, Israel*

emails: zuckers@cs.bgu.ac.il

Abstract

Given a graph G and positive integers b and w, the black-and-white coloring problem asks about the existence of a partial vertex-coloring of G, with b vertices colored black and w white, such that there is no edge between a black and a white vertex. This problem is known to be NP-complete in general. We provide here a polynomial time approximation algorithm for the optimization version of the problem.

Key words: black-and-white coloring problem, BWC problem, approximation algorithm.

1 Introduction

The *Black-and-White Coloring (BWC) problem* is defined as follows. Given an undirected graph G and positive integers b, w, determine whether there exists a partial coloring of G such that b vertices are colored black and w vertices white (with all other vertices left uncolored), such that no black vertex and white vertex are adjacent. Such a partial coloring, if exists, is a *Black-and-White Coloring (BWC)* of the graph.

One application of the BWC problem comes from the chemical industry. A set of b samples of a product B and w samples of a product W has to be stored in $n \geq x + y$ different available places. For security reasons, due to the chemical nature of the samples and the configuration of the storing places, there are certain pairs of places that cannot contain two different types of products. The question is whether it is possible to store all samples by respecting these restrictions. By constructing a graph G that has a vertex for each storing place and an edge between each two places that are not allowed to contain two different types of products, this problem reduces to the BWC problem.

Another application is solved explicitly in [1]: Items of two data types, D_1 and D_2, are stored in a 2-dimensional table. A person would like to retrieve data of type D_1 or of type

 ISBN: 978-84-617-8694-7

D_2, but not of both. When retrieving data, we would like to allow a one-unit error in each of the table's indexes. In case of an error, we do not want a person trying to retrieve an element of type D_1 to extract an element of type D_2. An additional goal is to populate the elements of type D_1 in a way that will maximize the number of places left in the table for the elements of type D_2.

The problem was originated by Berge, who raised the following instance [4].

Problem 1.1 *Given positive integers n and $b \leq n^2$, place b black and w white queens on an $n \times n$ chessboard, so that no black queen and white queen attack each other, and with w as large as possible.*

The BWC problem has two natural corresponding optimization problems:

1. Given a graph G and a positive integer b, color b of the vertices black, so that there will remain as many vertices as possible which are non-adjacent to any of the b vertices. These latter vertices are to be colored white, and the resulting coloring is *optimal*. All other vertices are to be left uncolored.

2. Given a graph G and a positive integer b, color b of the vertices black, while all other vertices are to be colored white, in a way that there will be as few as possible edges connecting black and white vertices. In this optimization version, we should make the BWC as legal as possible, meaning, we would like to reduce the number of "erroneous" edges, i.e., edges connecting black and white vertices.

The BWC problem has been introduced in general, and proved to be NP-complete, by Hansen *et al.* [4]. In the same paper, an $O(n^3)$ algorithm for trees was given. In [2], an $O(n^2 \lg^3 n)$ algorithm for trees was given. Kobler *et al.* [5] gave a polynomial algorithm for partial k-trees with a fixed k. In [7], there is an algorithm for chordal graphs, which is $O(\chi n^3)$ time, where χ is the chromatic number of the graph.

Yahalom [6] investigated an analogous problem to that suggested by Berge, using rooks instead of queens, and gave a sub-linear algorithm to this problem. For special cases, in which the ratio between the sides of the board is an integer or close to an integer, she derived an explicit formula for the optimal solution. In [1], we investigated an analogous problem, using kings instead of queens, and provided explicit optimal solutions for the toroidal and the non-toroidal versions.

In [3] we examined several heuristic algorithms, in particular tabu search, for solving the problem in general.

The BWC problem admits a generalization for any number of colors. An *anticoloring* of a graph is a partial vertex coloring with two or more colors, in which no two adjacent vertices have distinct colors. In the general *anticoloring problem*, we are given an undirected graph G and positive integers $b_1, \ldots, b_k$, and have to determine whether there exists an anticoloring of G such that b_j vertices are colored in color j, $j = 1, \ldots, k$. We call such an anticoloring

 ISBN: 978-84-617-8694-7

a $(b_1, \ldots, b_k)$-anticoloring. Yahalom [6] noticed that it is easy to rewrite the anticoloring problem as an integer linear programming problem.

In this paper we focus on the second optimization version of the problem and present a polynomial-time approximation algorithm for it.

2 Results

Consider the following optimization version of the BWC problem,

Problem 2.1 *Given a graph G and a positive integer b, color b of the vertices black, while the rest of the vertices are to be colored white, in such a way that the number of "correct" edges, i.e, edges connecting vertices colored with the same color, is maximal.*

Note that, since all vertices are colored black or white, in case G is connected, there should be at least one "erroneous" edge.

Obviously, since the number of edges $|E|$ is given, the problem of finding a coloring with maximal correct edges is equivalent to the problem of finding a coloring with minimal erroneous edges. Thus, Problem 2.1 is equivalent to the definition we presented in Section 1.

Consider the following

Algorithm 2.1 *Given a graph $G = (V, E)$ and an integer $b \leq |V|$, choose randomly b vertices to be colored black. All other vertices are to be colored white.*

We will show

Theorem 2.2 *Algorithm 2.1 is a polynomial $\frac{1}{2}$-approximation algorithm for Problem 2.1.*

Proof:
Obviously, the algorithm has a polynomial time. Now, since the graph G contains n vertices, the probability for a vertex to be colored black is $\frac{b}{n}$. The probability for an edge to connect a black and a white vertices is

$$2 \cdot \frac{b}{n} \cdot (1 - \frac{b}{n}) = \frac{2b(n-b)}{n^2}.$$

A simple calculation shows that this function gets a maximum value where $b = \frac{n}{2}$. In this case, the maximum value is $\frac{1}{2}$. Therefore, the probability for an edge to connect a black and a white vertex (i.e., erroneous edge) is at most $\frac{1}{2}$. Surely, the probability for the opposite case, in which an edge is to be correct, is at least $\frac{1}{2}$. Therefore, the expected number of correct edges is at least $\frac{|E|}{2}$. The optimal solution contains at most $|E|$ correct edges. Thus, Algorithm 2.1 gives a $\frac{1}{2}$-approximation for Problem 2.1.

Note that this happens in the worst case. In most cases, where $b < |V|$ or $b > |V|$, the expected number of correct edges would be much greater than $\frac{|E|}{2}$, and therefore the approximation ratio would be much better.

 ISBN: 978-84-617-8694-7

3 Future work

We plan to find a better approximation algorithm for the problem, or prove that in the worst case there is no such. We also plan to find an algorithm for the online version of the problem, in which the graph is not given in advance, and we should color each vertex before the next one arrives.

Abstract

Gas transportation via long pipelines is considered. Distributed parameter modelling with series and shunt energy dissipation and gas stream capacitance and inductance is incorporated. Hybrid analysis methods, wherein both the distributed and the lumped, concentrated elements of the pipeline system are included in the overall model, are advocated. An illustrative application study is outlined validating thereby the algebraic procedures employed.

Key words: gas, pipeline, transient, modelling, response

i. Introduction

The transportation of gas over long distances by pipelines will be considered in this contribution. This method of supply is a relatively safe, reliable and cost- effective form of conveying natural gas which is universally employed.
Constructing and the installation of gas pipelines is an expensive, labour intensive and politically sensitive operation. These networks often span remote regions, cross national boundaries and ecologically protected areas resulting in delicate, protracted negotiations.
Beyond this the running cost associated with gas pipelines is substantial. Owing to the frictional energy dissipation arising from the internal pipeline roughness, welds, joints, bends and discontinuities, there is a continuous reduction in the gas stream pressure an hence, volume gas steam flow rate. To counter this effect, centrifugal or axial flow compressors are installed at strategic locations along the pipeline restoring thereby the pressure loss and gas volume flow rate.

Due to the length of gas pipelines and the proportional pressure loss, the compressors employed operate continuously. Consequently, the running cost, maintenance and refit charges associated with this requirement, are substantial.

This problem is exacerbated by the remote locations, monitoring and operation of the compressor drive systems and gas coolers. These active devices must also respond to varying load demands with the requirement for constant delivery pressure and supply rates.

As with all continuously operated systems, any operational economy is translated into significant savings owing to the accumulating reduction in running, maintenance and delivery costs. However, to assess the energy efficiency of the system modelling procedures have to be derive enabling the dynamic system response to be investigated.

The classical theory for spatially dispersed pipeline systems results in irrational, multivariable, input- output models which are incomplete in the Laplace transform variable, see for example [1], [2]. Theoretically, it is possible to obtain the predicted, system responses from these models. However, the procedures involved do not provide simple, usable results which can be incorporated into design, analysis or optimisation investigations.

Finite element techniques may be used to assess the pipeline dynamics. With this procedure, large matrix models arise from the modelling procedure attracting thereby computational errors. Considerable speculation surrounding the computed pipeline performance may also be encountered in that the number and composition of the elements employed is unspecified.

In view of this, the focus of this contribution will be on deriving a pipeline modelling method which includes all of the salient features of classical analysis whilst avoiding the above complications.

ii. Long Pipeline Modelling Methods

In the transportation of gases via long pipeline and compressor networks, geographical dispersion is a significant feature. Owing to this, obtaining estimates for the volume flow of gas using conventional, lumped parameter theory is inappropriate.

It may be considered that using multiple lumping, with the application of finite element techniques, would be sufficient. However, this is not so, since the dynamics of spatially dispersed systems comprise a combination of travelling, stationary and reflected pressure and flow waveforms. Hence, there is no equivalent lumped, cascaded model counterpart since travelling and reflected transient components cannot materialise in lumped representations, in that all spatial dispersion effects are absent, from these models.

In any case when considering pipelines of 1-10 km in length, the matrix models, derived from fe methods, would be dimensionally very large [3]. Consequently, in

addition to the analytical disadvantages cited above, numerical computational errors which would further contaminate the results would be encountered [4].

Alternatively, with the employment of hybrid, distributed- lumped modelling an accurate modelling method is available [5], [6]. This procedure allows pipeline elements which are clearly distributed, to be modelled using distributed parameter methods. Otherwise, relatively pointwise components and sub - assemblies such as valves, compressors, bends and restrictions may be represented using lumped analysis methods without too much loss of accuracy. This allows engineering judgment to be exercised in selecting the appropriate modelling method, for each system element.

Importantly, the many boundary conditions and complexity arising from the use of distributed parameter methods universally are avoided with this approach, whilst including simple lumped parameter models for components which form the pipeline connecting elements and series- parallel branches.

Following the modelling of the individual elements of pipelines, distributed-lumped analysis allows the construction of an overall hybrid, matrix representation for the system. The final model provides a general, component identifiable, accurate, impedance- admittance realisation enabling dynamic simulation, analysis and regulator design.

iii. Series and Parallel Representations

Elements comprising an overall pipeline system may be assembled in series, parallel or in series parallel form where in each case, the steady state volume flow would be inversely proportional to the pipeline input impedance.

In the analysis herein, lumped parameter components are represented by simple frictional flow resistances R_1, R_2, R_3 etc. However, there is no need to adhere to this configuration. Any analogous two port network representation could be employed to model the lumped parameter units.

For the connecting elements, where there is energy storage, modelling using two port network analogues which contain inductance and capacitance elements, as shown in [7], could be employed.

iv. Distributed Parameter Modelling

Although the flow of gas, in pipeline systems is usually turbulent, three dimensional and non-linear, there are compelling reasons for the formulation of simple, usable models for perturbed flow changes, relative to given steady state conditions. Essentially, this type of model would enable the analysis of complex, inter connected applications to be analysed. This ideally would be via general solutions for the spatially distributed, pressure - flow relationships following input or disturbance changes. Moreover, simulation studies could be easily accommodated

using this form of representation with the advantage that regulator design exercises could now be embarked upon using existing theoretical techniques and algorithms.

In fact pioneering work, as detailed in [8], [9] and [10], showed that theoretically derived, first order, perturbed, acoustic, one dimensional approximations for the Navier-Stokes equations were available. These modelling restrictions included zero bulk modulus and radiant heat transfer effects. A continuous, homogenous medium was also assumed with no radial or axial heat transfer effects.

Further work within this framework was undertaken in [11] where a general discrete, distributed-lumped parameter representation, for linear systems was presented. Low temperature application studies using this approach were proposed in [12] where all of these representations related to the perturbed, pressure variation dynamics, relative to steady state, equilibrium conditions.

Extending this work, this contribution focuses on the distributed parameter system model shown in [1] and [2], where L_j, C_j, r_j and g_j are the pipeline system equivalent, distributed inductance, capacitance and series (longitudinal) and shunt (radial) flow resistance and conductance, per metre length of pipeline, respectively. The governing equations for this type of element, for the *j*th pipeline section are:

$$\frac{\partial p_j}{\partial x}(t,x) = -L_j \frac{\partial q_j}{\partial t} - r_j q_j(t,x) \tag{4.1}$$

and

$$\frac{\partial q_j}{\partial x}(t,x) = -C_j \frac{\partial p_j}{\partial t} - g_j p_j(t,x) \tag{4.2}$$

Following Laplace transformation, with zero initial conditions, equations 4.1 and 4.2 yield the solution, for the *j*th distributed parameter model of a system of *m* elements, of:

$$\begin{bmatrix} P_j(s,l_j) \\ P_{j+1}(s,l_{j+1}) \end{bmatrix} = \begin{bmatrix} \zeta_j^{-1}(s)(s)\mathrm{w}_j(s) & -\zeta_j^{-1}(s)\left(\mathrm{w}_j^2(s)-1\right)^{1/2} \\ \zeta_j^{-1}(s)\left(\mathrm{w}_j^2(s)-1\right)^{1/2} & -\zeta_j^{-1}(s)\mathrm{w}_j(s) \end{bmatrix} \begin{bmatrix} Q_j(s,l_j) \\ Q_{j+1}(s,l_{j+1}) \end{bmatrix} \tag{4.3}$$

where: $j = 2k+1,\ k = 0,1,\cdots m-1,$

($m =$ Number of distributed parameter elements),

$$\zeta_j(s) = \left[\left(L_j s + r_j\right)/\left(C_j s + g_j\right)\right]^{1/2}, \quad w_j(s) = \left(e^{2\Gamma_j(s)l_j}+1\right)/\left(e^{2\Gamma_j(s)l_j}-1\right)$$

and: $\Gamma_j(s) = \left[\left(L_j s + r_j\right)\left(C_j s + g_j\right)\right]^{1/2}$

Consequently, even with all of the constraints mentioned earlier the input-output relationship for a typical distributed parameter, gas pipeline network model is multivariable, irrational and is incomplete in the Laplace variable *s*. This difficulty effectively masks any correspondence between the actual system performance and

the governing equations so that extracting information from this representation is markedly impaired, see for example [13].

In this regard, of interest here, is the nature of the series impedance and shunt admittance of the infinitesimal airway element, shown in [1]. The series impedance frictional drag r_j, for example, represents the effect of the gas flow on the pressure gradient arising from shear action, at the pipeline wall, boundary layer. Contrasting this, the shunt g_j, admittance or conductance arises from compressibility effects, as shown in [14] where the frictional drag arises from varying gas path compliance, owing to cross-flow turbulence and molecular friction.
In pipeline systems, the flow impedance is principally due the entrance/ exit losses and to the r_j and g_j, distributed pipeline frictional resistance effects where:

$$\frac{1}{g_j} > r_j \tag{4.4}$$

In dimensionally "long" pipelines both the series r_j and the shunt g_j frictional factors, contribute to the overall pressure drop and diminishing volume flow characteristics. The analysis herein also confirms that the inclusion of both these dissipation mechanism is mandatory. Moreover, the per unit length energy storage parameters, as shown in [15] and [16], for a circular pipeline, diameter $2a_j$ are the gas path capacitance and inductance of:

$$C_j = \pi a_j^2 \Big/ \gamma R_g \theta_j \rho \tag{4.5}$$

and

$$L_j = 1 \Big/ \pi a_j^2 \rho, \text{ respectively, where:} \tag{4.6}$$

$$L_j >> C_j \tag{4.7}$$

for engineering applications. In view of the inequalities of equation 4.4 and 4.7 rationality may be recovered by equating:

$$\left(\frac{C_j s}{g_j}+1\right)\frac{\prod_{k=1}^{L}\left(T_{jk}s+1\right)^2}{\prod_{k=1}^{L}\left(\tau_{jk}s+1\right)^2} \cong \left(\frac{L_j s}{r_j}+1\right) \tag{4.8}$$

It should be noted that for the j^{th} section, with an appropriate choice of T_{jk} and τ_{jk} the approximation of equation 4.8, with $s = i\omega$, is accurate at:

low frequencies $\omega < r_j / L_j$, high frequencies $\omega > g_j / C_j$

and at $(2l-1)$ intermediate frequencies ω^* where:

$r_j \Big/ L_j < \omega^* < g_j \Big/ C_j$ Then since:

$$\Gamma_j(s)=\left[r_j\left(\frac{L_j s}{r_j}+1\right)\left(\frac{C_j s}{g_j}+1\right)g_j\right]^{1/2}, \tag{4.9}$$

equation 4.9 becomes, following the substitution shown in equation 4.8:

$$\Gamma_j(s)=\alpha_j\frac{\left(T_{j1}s+1\right)}{\left(\tau_{j1}s+1\right)}\frac{\left(T_{j2}s+1\right)}{\left(\tau_{j2}s+1\right)}\left(\frac{C_j s}{g_j}+1\right) \tag{4.10}$$

where: $\alpha_j=\sqrt{r_j g_j}$

Equally, since:

$$\zeta_j(s)=\sqrt{\frac{\left(L_j s+r_j\right)}{\left(C_j s+g_j\right)}} \tag{4.11}$$

then equation 4.11, with the substitution of equation 4.8, continuing with L=2 for illustration purposes, is:

$$\zeta_j(s)=\bar{\alpha}_j\frac{\left(T_{j1}s+1\right)}{\left(\tau_{j1}s+1\right)}\frac{\left(T_{j2}s+1\right)}{\left(\tau_{j2}s+1\right)},\quad \text{where } \bar{\alpha}_j=\sqrt{\frac{r_j}{g_j}} \tag{4.12}$$

The remaining important function of equation 4.2 is $w_j(s)$. Since;

$$w_j(s)=\left(e^{2l_j\Gamma_j(s)}+1\right)\Big/\left(e^{2l_j\Gamma_j(s)}-1\right) \tag{4.13}$$

then with $\Gamma_j(s)$ from equation 4.10:

$$w_j(s)=\left(e^{2l_j\sqrt{r_j g_j}\chi_j(s)}+1\right)\Big/\left(e^{2l_j\sqrt{r_j g_j}\chi_j(s)}-1\right) \tag{4.14}$$

Consequently, upon substituting for equation 4.14:

$$\left(w_j^2(s)-1\right)^{1/2}=2e^{l_j\sqrt{r_j g_j}\chi_j(s)}\Big/\left(e^{2l_j\sqrt{r_j g_j}\chi_j(s)}-1\right) \tag{4.15}$$

where in equation 4.15:

$$\chi_j(s)=\frac{\left(T_{j1}s+1\right)}{\left(\tau_{j1}s+1\right)}\frac{\left(T_{j2}s+1\right)}{\left(\tau_{j2}s+1\right)}\left(\frac{C_j s}{g_j}+1\right) \tag{4.16}$$

given by: $\chi_j\cong a_j s+b_j$ (4.17)

where from equation 4.17, expanding $\chi(s)$ for high frequencies gives:

$a_j=\left[\frac{C_j}{g_j}+\left(T_{j1}+T_{j2}\right)-\left(\tau_{j1}+\tau_{j2}\right)\right]$ and $b_j=1$

It is evident from equations 4.13, through to equation 4.17, that the distributed parameter model is now in an attractive form. The functions comprising equation 4.3 are free from origin branch point problems with each component $\zeta_j(s)$, $w_j(s)$ and $\left(w_j^2(s)-1\right)^{1/2}$ being single valued and complete, in the Laplace variable s with simple steady state values of:

$$\zeta_j(0)=\bar{\alpha}_j,\ w_j(0)=\frac{e^{2l_j\alpha_j\chi_j(0)}+1}{e^{2l_j\alpha_j\chi_j(0)}-1}\ \text{and}\ \left(w_j^2(0)-1\right)^{1/2}=\frac{2e^{l_j\alpha_j\chi_j(0)}}{e^{2l_j\alpha_j\chi_j(0)}-1}$$

Although values for the equivalent of the energy storage via the distributed capacitance and inductance per unit length in gas pipelines can be obtained with accuracy, from equations 4.5 and 4.6, the distributed, per unit length, series and shunt resistance values are more difficult to ascertain. From the theory of fluid dynamics the pressure drop due to friction is inversely proportioned to the Reynolds number, $\mathrm{Re}<2500,$ for a given gas flow velocity, gas density, ducting length and cross sectional area. For higher Reynolds numbers the empirical law of Blasius could be used to obtain estimates of frictional flow coefficients, as discussed in [17]. These estimates and those obtained from Moody diagrams [18] however, are based on steady flow conditions, in ducting of constant cross sectional area. Consequently, as in all engineering system problems, the frictional coefficient values are known with least confidence. Empirically based results, derived from direct measurement may be used if the system exists. Otherwise, upper and lower bounded values for r_j and g_j may be employed, with the system response characteristics reflecting these estimates.

v. An Overall Pipeline System Model

An overall model structure must now be derived enabling the assembly of the system matrix. For purposes of illustration, if a distributed- lumped configuration is assumed, then an appropriate system matrix can be constructed by adding consecutive distributed or lumped system descriptions and in so doing, eliminate all intermediate variables.

In this case the system model for a total of *m* distributed-lumped, interconnected sections for the system equation:

$$\left(P_1(s),0,0\cdots0\right)^T=\Omega(s)\left(Q_1(s),Q_2(s),\cdots,Q_m(s)\right) \tag{5.1}$$

where:

$$\Omega(s)=\begin{bmatrix}
\zeta_1(s)\mathrm{w}_1(s) & -\zeta_1(s)\left(\mathrm{w}_1^2(s)-1\right)^{1/2} & 0 & 0 & \cdots\\
\zeta_1(s)\left(\mathrm{w}_1^2(s)-1\right)^{1/2} & -\zeta_1(s)\mathrm{w}_1(s)-\bar{g}_{1,11}(s) & -g_{1,12}(s) & 0 & \cdots\\
0 & -g_{1,12}(s) & -\bar{g}_{1,22}(s)+\zeta_2(s)\mathrm{w}_2(s) & \zeta_2(s)\left(\mathrm{w}_2^2(s)-1\right)^{1/2} & \cdots\\
0 & 0 & \zeta_2(s)\left(\mathrm{w}_2^2(s)-1\right)^{1/2} & -\zeta_2(s)\mathrm{w}_2(s)-\bar{g}_{3,11}(s) & \cdots\\
\vdots & \vdots & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0
\end{bmatrix}$$

can be easily constructed. This impedance matrix is in respect of the distributed-lumped-distributed-lumped-system topology with $\bar{g}_{1,11}(s)$, $\bar{g}_{1,22}$ etc., being the diagonal elements of the termination matrix of equation A2.1. However, there is no

restriction on assembling alternative matrix descriptions for distributed-distributed-distributed realizations, for example, when modelling a series of purely distributed parameter pipeline elements, of varying dimensions.
As equation 5.1 shows, $\Omega(s)$ is a skew, symmetric tri-diagonal matrix enabling simple recursive procedures to be employed in the computational of the determinant, as shown in [21].

vi. Single Pipeline and Compressor

In this application a model representing a single, long pipeline and a compressor will be considered.
From the theory of section 5, the system equation 5.1 is relevant, since there is only a single distributed parameter section and a single termination, lumped resistance element. Hence:

$$\begin{bmatrix} P_1(s) \\ P_2(s) \end{bmatrix} = \begin{bmatrix} \zeta(s)\mathrm{w}(s) & -\zeta(s)\left(\mathrm{w}^2(s)-1\right)^{1/2} \\ \zeta(s)\left(\mathrm{w}^2(s)-1\right)^{1/2} & -\zeta(s)\mathrm{w}(s) \end{bmatrix} \begin{bmatrix} Q_1(s) \\ Q_2(s) \end{bmatrix} \tag{6.1}$$

where in equation 6.1, the termination relationship between the transformed pressure change $P_2(s)$ and the transformed airflow change $Q_2(s)$ is simply:

$$P_2(s) = RQ_2(s)$$

Consequently, following inversion equation 6.1 becomes:

$$\frac{\begin{bmatrix} \zeta(s)\mathrm{w}(s)+R & -\zeta(s)\left(\mathrm{w}^2(s)-1\right)^{1/2} \\ \zeta(s)\left(\mathrm{w}^2(s)-1\right)^{1/2} & -\zeta(s)\mathrm{w}(s) \end{bmatrix}}{\zeta(s)\left(\mathrm{w}(s)R+\zeta(s)\right)} \begin{bmatrix} P_1(s) \\ 0 \end{bmatrix} = \begin{bmatrix} Q_1(s) \\ Q_2(s) \end{bmatrix} \tag{6.2}$$

If the compressor unit is assumed to be relatively lumped, in comparison to the pipeline, comprising rotors and bearings, see for example [22] then:

$$P_1(s) = k_f U(s) \Big/ \left(\tau_f(s)+1\right)$$

where: k_f is the gain and τ_f is the fan time constant and $U(s)$ is the applied voltage for the electrical drive. For this particular application, the parameters are:

a = Pipeline raduis $= 0.5\mathrm{m}$, Θ = Absolute Gas Tempreture $= 313\mathrm{K}^{\circ}$, ρ = Gas density

R = Exit resistance $= 1.0\ \mathrm{Nsec/m^5}$, R_g = Characteristic gas constant $= 287\ \mathrm{J/kg\ K^{\circ}}$

l = Pipeline length $= 1000$, 5000 and 10,000 m, τ_c = Compressor time constant $= 5.0$ sec

k_c = Compressor gain $= 10\ \mathrm{kg\ sec^2/m^3v}$, γ = Adiabatic index $= 1.31$

g = Shunt conductance per meter $= 10^{-4}\ \mathrm{m^5/Nsec}$, r = Series resistance per meter $= 0.6\times10^{-4}\ \mathrm{Nsec/m^5}$

From equations 4.5 and 4.6 the gas capacitance and inductance per meter length of pipeline are:

$C = \pi a^2 / \gamma R_g \Theta \rho = 0.643 \times 10^{-4}$ m^{2}and: $L = 1/\pi a^2 \rho = 1.2835$ m^2, respectively.

From equations 4.10 and 4.12, and 4.11, respectively:

$$\bar{\alpha} = \sqrt{(r/g)} = 0.7745,\ \alpha = \sqrt{rg} = 0.7745 \times 10^{-4} \text{ and } \zeta(s) = \bar{\alpha}\left(\frac{T_1 s + 1}{\tau_1 s + 1}\right)\left(\frac{T_2 s + 1}{\tau_2 s + 1}\right)$$

Also equation 4.8 requires that for a single pipeline section where for illustration purposes, l = 2 and the section subscripts j have been dropped:

$$\left(\frac{T_1 s + 1}{\tau_1 s + 1}\right)\frac{(T_2 s + 1)^2}{(\tau_2 s + 1)^2} \cong \frac{L/r\, s + 1}{C/g\, s + 1} \tag{6.3}$$

where here: $L/r = 2.1392 \times 10^4$ sec and $C/g = 0.0643$ sec

From the Bode diagram shown in figure 3, where the frequency response curves for:

$$\left(L/r\, i\omega + 1\right)\Big/\left(C/g\, i\omega + 1\right) \text{ and } \frac{(T_1 i\omega + 1)(T_2 i\omega + 1)}{(\tau_1 i\omega + 1)(\tau_2 i\omega + 1)}$$

are shown in full and dotted lines, respectively, for the series resistance of: $r = 0.6 \times 10^{-4}$ Nsec/m^5 with a shunt admittance of $g = 10^{-4}$ m^5/Nsec.

The break frequencies selected for the Bode characteristics for $1/(L/r)$, $1/(C/g)$, $1/T_1$, $1/T_2$, $1/\tau_1$ and $1/\tau_2$ are presented in Table 1, below:

r Nsec/m^5	$1/(L/r)$ rad/sec	$1/(C/g)$ rad/sec	$1/T_1$ $1/T_2$ rad/sec	$1/\tau_1$ $1/\tau_2$ rad/sec
0.6x10^{-4}	0.4674x10^{-4}	15.552	6x10^{-4} 0.4	0.05 6.02

Table 1, Break frequencies $(g = 10^{-4}$ m^5/Nsec)

It is evident, from figure 1, that the approximations has the mid-range frequency intersection and exact low and high frequency correspondence, as stated earlier.

If now, as in equation 4.16,

$$\chi(s) = \frac{(T_1 s + 1)(T_2 s + 1)}{(\tau_1 s + 1)(\tau_2 s + 1)}\left(\frac{C}{g} s + 1\right) \tag{6.4}$$

is evaluated for the values in Table 1, then $w(s)$ and $\zeta(s)$, in equation 6.1, are fully defined and outputs may now be computed from this equation, where:

$$\frac{Q_1(s)}{P_1(s)} = \left(\zeta(s)w(s) + R\right)\Big/\left(\zeta(s)\left(w(s)R + \zeta(s)\right)\right) \tag{6.5}$$

$$\frac{Q_2(s)}{P_1(s)} = \left(w^2(s) - 1\right)^{1/2}\Big/\left(w(s)R + \zeta(s)\right) \tag{7.5}$$

where in delay form $w(s)=\left(1+e^{-2l\alpha\chi(s)}\right)\Big/\left(1-e^{-2l\alpha\chi(s)}\right)$, and $\hat{w}(s)=\left(w^2(s)-1\right)^{1/2}=\dfrac{2e^{-l\alpha x(s)}}{\left(1-e^{-2l\alpha x(s)}\right)}$

Alternatively, commensurate with the pipeline system topology, shown in figure 2, equations 7.4 and 7.5 may be written as:

$$\frac{Q_1(s)}{P_1(s)}=\frac{\left(\zeta(s)w(s)+R\right)}{\zeta(s)\left(w(s)R+\zeta(s)\right)} \tag{7.6}$$

and

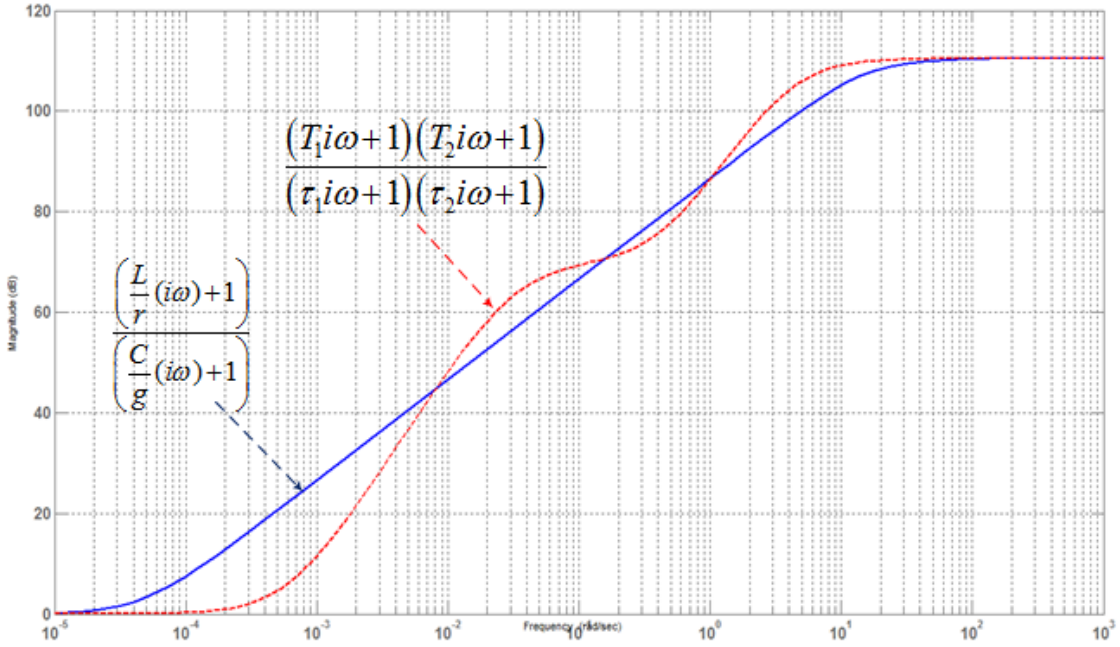

Figure 1, Bode Diagram Modulus for $\frac{\left(\frac{L}{r}(i\omega)+1\right)}{\left(\frac{C}{g}(i\omega)+1\right)}$ **and** $\frac{(T_1 i\omega+1)(T_2 i\omega+1)}{(\tau_1 i\omega+1)(\tau_2 i\omega+1)}$

$$\frac{Q_2(s)}{Q_1(s)}=\frac{\zeta(s)\left(w^2(s)-1\right)^{1/2}}{\left(\zeta(s)w(s)+R\right)} \tag{7.7}$$

The block diagram for the representation given by equations 7.6 and 7.7 is as shown in figure 2, which is in series form and whereas equations 7.4 and 7.5 provide the parallel equivalent realisation, for this system model.

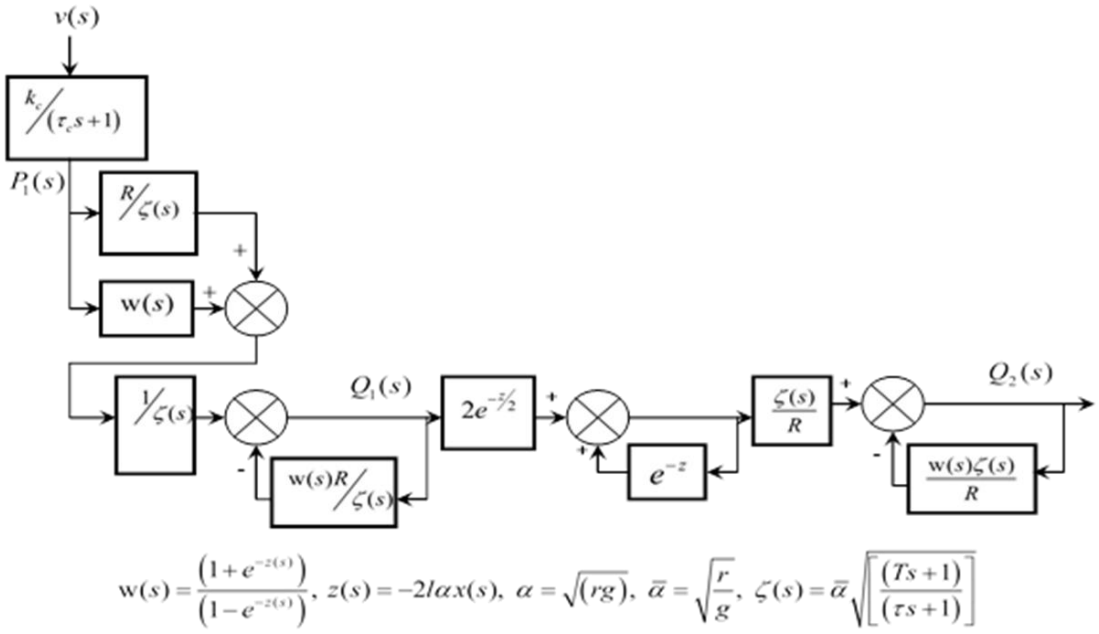

Figure 2, Distributed-Lumped Parameter Series Representation Block Diagram for a Pipeline and Compressor, *l* = 1000, 5000 and 10,000 m

To simplify the simulation process it would be prudent to construct sub-system, blocks for $w(s)$ and $\hat{w}(s)$. Since, from equation 4.17:

$\chi(s) = as + b$

where the low frequency approximation is:

$$a = \frac{C}{g} + \left(T_1 + T_2\right) - \left(\tau_1 + \tau_2\right) \text{ and } b = 1, \tag{7.8}$$

so that:

$$w(s) = \frac{\left(1 + e^{-2l\alpha(as+b)}\right)}{\left(1 - e^{-2l\alpha(as+b)}\right)} \tag{7.9}$$

Following a step input change on the $w(s)$ sub-system, it is easy to show that:

$$\frac{w(s)}{s} = \frac{1}{s}\left(1 + 2\sum_{n=1}^{\infty} e^{-2nl\alpha(as+b)}\right)$$

so that the output following any arbitrary finite input change would be stable since:

$b > 0$

From the geometry of the approximation given by equation 4.8, evidently:

$\left(T_1 + T_2\right) > \left(\tau_1 + \tau_2\right)$, so that, $a > 0$

resulting in the finite time delay $e^{-2l\alpha a}$ Also, for $\hat{w}(s)$, in delay form is:

$$\hat{w}(s) = \frac{2e^{-l\alpha(as+b)}}{\left(1 - e^{-2l\alpha(as+b)}\right)} \tag{7.10}$$

then following a unit step change on this sub-system:

$\frac{\hat{w}(s)}{s} = \frac{1}{s}\sum_{n=1}^{\infty} e^{-nl\alpha(as+b)}$ and this produces a stable output response since again:

$b > 0$ and $a > 0$ gives a finite time delay $e^{-nl\alpha a}$ and attenuation $e^{-nl\alpha b}$.

In this case, in accordance with Table 1, when: $r = 0.6\times10^{-4}$ Nsec/m^5

then following division the low frequency approximation from equation 7.8 is:

$\chi(s) = 1 + 1648.9s$ and $\zeta(s) = \bar{\alpha}\left(\frac{1666.6s+1}{20s+1}\right)\left(\frac{1.5s+1}{0.166s+1}\right)$

As the pipeline length varies, the characteristic impedance $\zeta(s)$, the exit resistance R and the compressor model remain invariant. Consequently, only $w(s)$ and $\hat{w}(s)$ need to be adjusted, in the simulation model, to obtain the gas flow characteristics for any length of pipeline with the same diameter and per unit length resistance values. In this regard, substituting for $\chi(s)$ in the equations for $w(s)$ and $\hat{w}(s)$ are given by equations 7.9 and 7.10.

Hence for the 1,000 m pipeline:

$w(s) = \frac{\left(1+0.8555e^{-77.0627s}\right)}{\left(1-0.8555e^{-77.0627s}\right)}$, $\hat{w}(s) = \frac{1.8508e^{-38.5813s}}{\left(1-0.8555e^{-77.0627s}\right)}$ for the 5,000 m pipeline:

$w(s) = \frac{\left(1+0.4609e^{-385.3s}\right)}{\left(1-0.4609e^{-385.3s}\right)}$, $\hat{w}(s) = \frac{1.3578e^{-192.5794s}}{\left(1-0.4609e^{-385.3s}\right)}$ and for the 10,000 m pipeline:

$w(s) = \frac{\left(1+0.2125e^{-770.62s}\right)}{\left(1-0.2125e^{-770.62s}\right)}$, $\hat{w}(s) = \frac{0.9218e^{-385.15s}}{\left(1-0.2125e^{-770.62s}\right)}$

The distributed – lumped parameter block representation for the series configuration including the compressor unit, given by: $\frac{P_1(s)}{v(s)} = \frac{k_c}{\tau_c s+1}$, is shown in figure 1. Following unit step changes on the compressor motor voltage input, the changes in the volume flow at $Q_1(t)$ and $Q_2(t)$ are shown in figure 3 in dotted and bold lines, respectively. This figure is initially for a 1000 m long, 1.0 m diameter, distributed parameter pipeline model, with $r = 0.6\times10^{-4}$ Nsec/m^5 and $g = 10^{-4}$ m^5 / Nsec, with the remaining parameters given earlier. Upon increasing the pipeline length to 5000 m and then 10,000 m the responses, following a 1% change in the compressor motor voltage, are as shown in this figure again with dotted and bold traces for the inlet and exit volume flow transients, respectively.

vii. Conclusion

In this contribution, the theory for modelling long pipelines was presented. It was shown that accurate, unambiguous, simple models could be easily constructed for pipeline – compressor configurations with the model-simulation block diagram

requiring with more than 4 basic sub-system models, for the compressor, $w(s), \left(w^2(s)-1\right)^{1/2}$ and $\zeta(s)$ for the complete system representation.

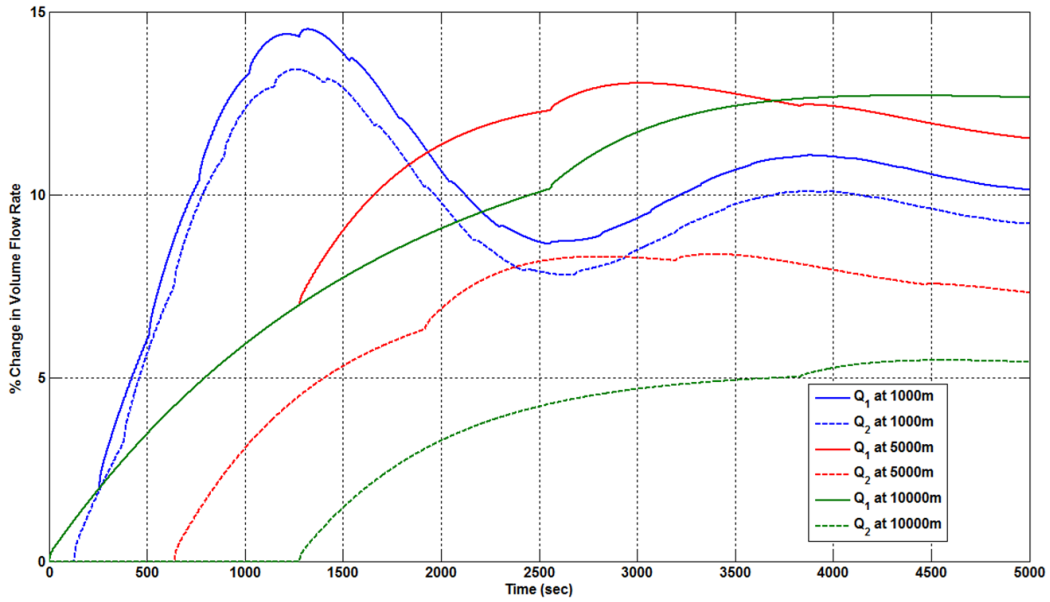

Figure 3, Percentage Changes in Inlet and Exit Pipeline Volume Flow Rates for 1m Diameter Gas Pipeline with an Exit Resistance of 1 N sec/m

The distributed parameter theory involved was also uncomplicated with the incorporation of the continuous series and shunt resistances and the gas stream capacitance and inductance, energy storage effects. Consequently, the perturbed transient volume flow responses following any input variation are ready available, from the theoretical development and simulation process, established herein.
The transient response representations for pipelines up to 10km were obtained from the application study. Owing to the generality of the theory pipelines with physical features could be accommodated.

viii. Acknowledgment

The author wishes to acknowledge the support and encouragement for this research provided by the Vice Chancellor, The British University in Dubai-UAE.

Abstract

The aluminium extrusion process is influenced by several parameters, such as the length and temperature of the billet, the extrusion speed, the extrusion ratio, the profiles temperature,. These parameters determine the quality of the product as well as the amount of scrap produced. In the bibliographic research, it was evident a strong relationship of dependency between the different variables being studied. This article's goal is to propose a set of improvements to reduce the percentage of scrap during the aluminium extrusion process and, consequently to increase the productivity and quality of the product commercialised by the company ADLA, S.A.

Thus, through this study, it is intended to obtain extrusion indicators that allow reduce the scrap percentage. So that in the future it is possible to settle which extrusion variables allow better results.

In a first stage, it is presented a brief introduction to the theme, the variables that influence the process are identified and the guidelines for the data collection are defined. After that, ANOVA and other statistical techniques are used to find out in which way the variables influence the scrap production.

Key words: Extrusion, Aluminium, Quality tools, Optimization, ANOVA
MSC2000: 62Pxx, 74Pxx

1. Introduction

According to Saha (2000), extrusion is a plastic deformation process in which a block of metal (billet) is forced to flow by compression through the die opening of a smaller cross-sectional area, as represented in Figure 1.

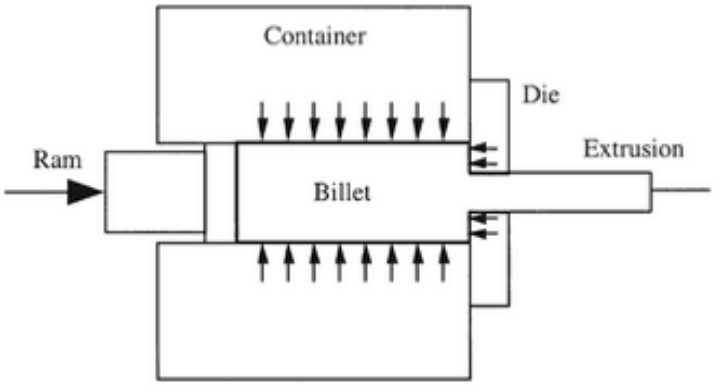

FIGURE 1 – Extrusion Process (Source: to Saha (2000))

The extrusion technology allows to produce varied geometry components, which can to be later applied in several areas (Shyamu *et al*, 2015, and Sreenivasulu and SrinivasaRao, 2016). This industrial process is used since the XIX century, but the high use of extrusion technique occurred in World War II, when different extruded aluminium profiles were used to produce aeronautical components (ABAL, 2007). Throughout the time, aluminium alloys have been widely studied and developed. Nowadays, the extruded aluminium profiles can be found in different markets such as construction, transports, motor sports, industry and structures, due to their excellent mechanical properties.

For the most demanding applications on the market is important predicting/controlling the properties of aluminum, if possible before, during and after extrusion. It allows collecting data, in order to improve the extrusion process, both in terms of optimization of equipment and inherent variables.

In order to face strong competition in all sectors and markets, it is necessary to move towards optimizing manufacturing processes, increasing competitiveness, reducing waste and maximizing profits. Thus, a key procedure is increasingly to attend the process quality improvement.

The main goal of this article is to obtain indicators that will allow us to optimise the fundamental parameters during the aluminium extrusion process, focus on the reducing of the scrap. Changing the experimental variables and checking the consequently response, is possible to understand their nature and the relationship between the variables. Our purpose is to produce improved products at the future in ADLA Aluminium Extrusion, SA company.

According to Bajimaya et. al. (2007) the properties of the extruded aluminium shapes are affected greatly by the way in which the metal flows during extrusion. Since, the metal flow is influenced by several factors, such as: temperature of billet, temperature of container, extrusion pressure, velocity of extrusion, size of billet (length and diameter) and extrusion ratio.
The length and temperature of the billet, the extrusion speed, the extrusion ratio and the profiles temperature are the variables process to have into account, in this study, because they are the actual available parameters in ADLA.
The application of statistical techniques to deal with the available variables are also an objective, in order to analyse their significance in the process.

2. Investigation hypothesis

In order to reach the proposed objective, a number of studies to examine the extrusion process and the variables that can influence it were carried out. In this section some research hypotheses has been formulated.

2.1. Billet length

Productivity can be define as the maximum amount of material, in good conditions, that can be produce per unit of time. Several studies have reported the importance of the billet length in the amount of scrap produced in the aluminium extrusion industry (Hajeeh, 2013; Tabucanon and Treewannakul, 1987).
Thus, the first hypothesis under investigation in this study is:

H1: The level of scrap produced is related to the length of the billet

2.2. Billet temperature

Several authors describe billet temperature as the key parameter in the aluminium extrusion industry, for example Flitta and Sheppard (2005) and Bajimaya, Park and Wang (2007). The temperature rise during extrusion depends on many parameters. Flitta and Sheppard (2005) affirms that the flow stress is reduced if the temperature is increased and deformation is therefore, easier, but at the same time, the maximum extrusion speed is reduced because localized temperature can lead to incipient melting temperature. Ab Rahim, Lajis and Ariffin (2015) affirms that the temperature of the billet is one of the variables to be taken into account during the extrusion process because it influences the quality of the extruded product and, therefore, it is connected to the amount of defective material. Given the below hypothesis (H2) is:

H2: The level of scrap produced is related to the temperature of the billet

2.3. Extrusion speed

The extrusion speed is a very important variable, because higher speed generates higher deformation/tension imposed into the billet inside the container. Consequently, increase the energy of the system, which will be converted to heat energy (Saha, 2000).

For a given profile extrusion, the speed of the press is considered to be one of the critical parameters. According to several authors, it is a variable that plays an important role, with respect to the surface quality of the profile and the productivity in the extrusion (Zhang et. al., 2012 and Flitta, 2004). According to Zhu, Couper and Dahle (2012) the extrusion temperature increases with increasing press speed, which directly influences the mechanical properties of the profile, as well as the surface quality of the product. However, the extrusion speed is limited by the appearance of tears on the surface of the extruded profile, which leads to an increase of non-conforming product (Arif et. al., 2002, and Li et. al., 2013). Thus, hypothesis 3 is:

H3: The level of scrap produced is related to the extrusion speed.

2.4. Extrusion ratio

The extrusion ratio (ER) of a profile is the clear indication of the amount of mechanical work that will occur during the extrusion of a given profile (Saha, 2000). This factor allows to calculate the effective deformation in the extrusion process (Extrusion Deformation = ln (ER)). It is expected that ER affects the flow stress of the metal and, consequently, also affects the maximum extrusion pressure (Karabay, Zeren and Yilmaz, 2003). It was not clear, in the literature, how the extrusion ratio influences the scrap production. However, according to some authors (Saha, 2000, and Karabay, Zeren and Yilmaz, 2003) it is well known that the increase in ER increases the maximum extrusion pressure.

Given the experience in ADLA, S.A. when the ER increased, the mechanical properties of the extruded profile are affected. The tensile strength increases as well as the hardness of the material increases, however a decrease in the percentage of elongation is observed. There is also an increase in the speed of the profile when the extrusion ratio is high, keeping the press speed constant during the extrusion process. Authors such as Abdul-Jawwad and Bashir (2011) indicate that ER directly influences the output temperature of the profile. If high temperatures influence the surface quality of the profile and its mechanical properties, we can consider that it has a relation with the levels of scrap produced. Thus, the 4 hypothesis is:

H4: The level of scrap produced is related to the extrusion ratio

2.5. Profile exit temperature

One of the main interests in the aluminium extrusion industry is to know the profile exit temperature, especially in alloys that are heat treated (6xxx series alloys). Such interest is due to the fact that the temperature of the profile at the exit of the press mouth influences in large part the obtaining of several characteristics and properties that determine the quality of the product, as the superficial quality of the product, hardness, resistance to traction and stretching (Abdul-Jawwad and Bashir, 2011).
The exit temperature is affected by several factors, namely the initial temperature of the billet, the extrusion speed, the heat generated during the extrusion due to the friction between the billet and the container (Flitta and Sheppard, 2005; Abdul-Jawwad and Bashir, 2011; Saha, 1998; and Farjad Bastani, Aukrust and Brandal, 2011). With regard to Saha (2000) the product quality is affected by the exit profile temperature, because influences the heat treatment processes and dimensional stability, causing defects during extrusion. These defects occur, according to Arif (2002), due to the fact that the high exit profile temperature leads to tears and a "*somewhat shaky*" appearance during extrusion of the profile.
In this way is predicted that the exit temperature of the profile influences the percentage of scrap produced. Then, hypothesis 5 is:

H5: The level of scrap produced is related to the profile exit temperature.

3. Results and Discussion

The experiments were carried out in an industrial extrusion press, having a maximal force of 25 MN and maximal ram speed of 20mm/s. Billet´s dimeter was Ø203,20 mm and was cuted behind the furnace.
These experiments were performed using five types of dies, with different dimensions and geometry (randomly chosen). During extrusion process several parameters were measured:

- billet length – L_{Bilet},
- billet temperature – T_{Bilet},
- extrusion speed – N,
- extrusion ratio – ER,
- profile exit temperature – T_{Exit}.

In order to verify the relationship between the extrusion process parameters similar to (Almeida, Correia and Costa, 2016) (considered as independent variables) and the percentage of scrap produced – %Scrap (dependent variable), a correlation matrix was calculated through the SPSS software.

From the obtained results, in Table 1, it was concluded that the variables *N* and T_{Exit} do not have a significant correlation with *%Scrap.* T_{Bilete} show a significant and positive correlation with the variable *%Scrap,* then we can consider that the billet temperature could be an explanatory element of a scrap increment during the aluminium extrusion process. On the other hand, the variables *ER* and L_{Bilet} has a significant and negative correlation with the *%Scrap,* then the billet length and extrusion ratio could be explanatories parameters of a scrap decrement during the aluminium extrusion process.

Table 1 – Pearson Correlations

		L_{Bilet}	T_{Bilet}	*N*	*ER*	T_{Exit}
%Scrap	Pearson Correlation	-0.398**	0.686**	0.096	-0.665**	0.043
	Sig. (2-tailed)	0.004	0.000	0.505	0.000	0.765
	n	50	50	50	50	50

*. Correlation is significant at the 0.05 level (2-tailed).

**. Correlation is significant at the 0.01 level (2-tailed).

According to this results we can consider verified the first, the second and the fourth investigation hypothesis, i.e., the level of scrap produced in this extrusion aluminium industrial process is related to the length of the billet, the temperature of the billet and the extrusion ratio.

In order to study if the relationships of the parameters under analysis affects the percentage of scrap, considering together, a multivariate linear regression model was tested in agreement with the hypothesis formulated. Then the dependent variable is the percentage of scrap and the extrusion parameters are the independent variables. In order to exclude non-significant parameters, the stepwise method is considered. The multivariate linear regression model summary is presented in Table 2.

Table 2 – Multivariate Linear Regression Model Summary

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
4	0.844[d]	0.712	0.686	5.08573

[d] Predictors: *(Constant),* T_{Bilet}, *ER,* L_{Bilet}, *N*

The model has an Adjusted R Square 0.686, then approximately 68.6%. From this way we can say that the four independent variables explain 68,6% of the variance occurred on the dependent variable % Scrap.

The significance value of the ANOVA test is approximately zero, Table 3, then the estimated linear multivariate model is highly significant, i.e., the variables have a significant effect on the variation of the dependent variable (%Scrap).

Table 3 – Multivariate Linear Regression ANOVA test

Model		Sum of Squares	df	Mean Square	F	Sig.
4	Regression	2870.702	4	717.676	27.747	0.000[e]
	Residual	1163.908	45	25.865		
	Total	4034.610	49			

[e] Predictors: *(Constant)*, T_{Bilet}, *ER*, L_{Bilet}, *N*

Table 4 – Coeficientes

Model	Unstandardized Coefficients		Standardized Coefficients	t	Sig.	Collinearity Statistics	
4	B	Std. Error	Beta				
(Constant)	-21.722	34.831		-0.624	0.536		
T_{Bilet}	0.166	0.071	0.259	2.346	0.023	0.526	1.903
ER	-0.131	0.024	-0.638	-5.383	0.000	0.456	2.193
L_{Bilet}	-0.022	0.006	-0.332	-3.843	0.000	0.860	1.162
N	-1.049	0.413	-0.238	-2.542	0.015	0.733	1.364

Finally, optimizing the extrusion process through better knowledge/control of the variables allows obtaining productivity gains, minimize the amount of waste and fundamentally improve the quality of the product. This is what we intend to achieve in the development of this work.

Abstract

Southern Spain is a region with its economy mostly based in the agriculture sector. New techniques for optimizing crops and post harvest processes are on the cutting-edge research lines. Andalusia (south of spain) is advancing fast in greenhouse technologies, seed optimization, harvest and post-harvest procedures. The industry must, in addition, optimize their expenses during the post-harvest process to avoid food loss and to be able to compute expenses to the producers that do not fit standards. This paper develops an embedded technology to analyse post-harvest products in order to compute potential food losses.

Key words: post-harvest, food loss, embedded system, parallel image analysis, homography.
MSC2000:

1. Introduction

Andalusia (southern Spain) is an eminently agricultural region. Southern Spain's industry has to be efficient both in terms of production and economy. Harvest and post-harvest are, therefore, highly optimized processes. The costs associated with post-harvest depend on how the product comes from the field. The state in which it arrives must be attributed to the costs of the producers.

Processing companies have complex, synchronized product lines and the fact that a product line has to be pre-processed causes the line to slow down, affecting the whole process of processing, packaging and distribution.

Figure 1. Distribution lines in a processing company (part of the production pipeline).

In [1] there is an interesting definition of what is a post-harvest system, and it is defined as a system that should be thought of as encompassing the delivery of a crop from the time and place of harvest to the time and place of consumption. Paying attention and efforts in reducing the food loss, obtaining the maximum efficiency and return in all the steps involved. This implies being able to calculate costs and risks in every element of the system.

The key term *system* denotes a dynamic, complex aggregate of logically interconnected functions or operations within a particular sphere of activity. The term *chain or pipeline* highlights the functional succession of various operations but tends to ignore their complex interaction. Figure 1 describes precisely how complex these systems can be. Distribution lines in Figure 1 are carefully scheduled according to the predicted production of the next day. The production is related to a certain producer. A producer has a risk associated. This paper will develop a mean to add more information to the risk of the producer whose product is on the distribution line.

In considering the system or the agro-food chain as a whole, harvesting can be seen as the hinge, or as a ridge between the pre-harvest slope, corresponding to production activity and the post-harvest slope, extending from harvesting to consumption. These ideas are illustrated in Figure 2, which give Bourne's graphic representation of the food pipeline. It should be noted that the producer is directly related to the pre-processing stage.

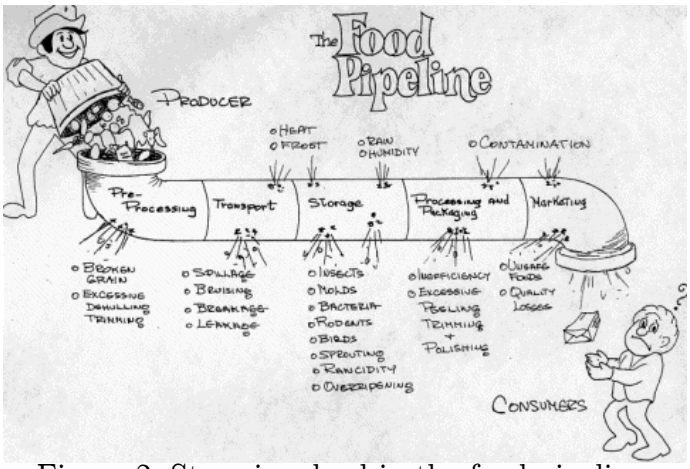

Figure 2. Steps involved in the food pipeline.

The post-harvest system encompasses a sequence of activities and operations that can be divided into two groups:

technical activities: harvesting, field drying, threshing, cleaning, additional drying, storage, processing;
economic activities: transporting, marketing, quality control, nutrition, extension, information and communication, administration and management.

Post-harvest losses

Losses are a measurable reduction in foodstuffs and may affect either quantity or quality. They arise from the fact that freshly harvested agricultural produce is a living thing that breathes and undergoes changes during post-harvest handling. Loss should not be confused with damage, which is the visible sign of deterioration, for example, chewed grain and can only be partial. Damage restricts the use of a product, whereas loss makes its use impossible.

The first distinction in agro-food losses is that between quantity and quality. Quantitative loss is a loss in terms of physical substance, meaning a reduction in weight and volume and can be assessed and measured. Qualitative loss, however, is concerned particularly with the food and reproductive value of products and requires a different kind of evaluation.
Damage is a clear deterioration in the product, e.g. broken or pitted grain, which affects more its quality than its quantity and can in the long-term result in a definite loss. Both damage and loss should be quantified in terms of weight and cost.

2. Materials and methods.

To deal with the food loss problems and to be able to calculate risks associated with each producer, it would be ideal to compute the damages or dirt that the fruit has when entering the line. This is an important point as if the product need pre-processing (such as cleaning) the production lines are slowed down. As this is the most worrying issue it is not the only problem that appears, also human intervention is planned to prepare the fruit.

The proposed solution is based in the analysis of a stream or sequence of images as captured from the CCD cameras incorporated in embedded devices. These embedded devices characterized by low powered processors, limited memory and connectivity are installed (as Figure 3 shows) in the head of production lines. A traditional issue regarding this approach is facing the computational concerns raised when processing the set of images. To this end advanced computational methods are needed.

When referring to set of images we have implemented and optimized efficient homography based analysis. As each tomato advances in the line it is rolled along its side. Cameras capture the computed unrolled surface and processes the damages or dirt on each piece. This is later sent to the cost system to advance risks in the production lines associated with each producer. The technique implemented to analyze the surface of each tomato is the image stitching - homography. In brief, an homography assume a camera takes two photographs--*a* and *b* of a set of points P_i. The camera's position is the same for the two photographs, but the orientation is different--in photograph *b* it has been rotated with the rotation matrix R. The image coordinates of the points P_i in the photographs will be related to each other with the affine transformation represented by a 3 by 3 homography matrix H

$$ {}^{a}\vec{p}_i = {}^{a}H_{b}\ {}^{b}\vec{p}_i $$

Figure 3. Production line transformation

If this matrix can be established, any point in *a* can be transformed to *b* and vice versa. That means that one of the photographs can be extended to contain everything that is seen by any of the cameras. More photographs can be added, and the extended photograph will grow to a bigger and more complete panorama image.

Image stitching has been solved in different ways and is widely commented in the literature [2]. The process of combining different images to one is used, for example to combine images taken by satellites for navigation, to generate panoramic views from impressive landscapes and huge objects [3], etc. Automatic image stitching can be automated through direct or feature-based methods. Direct methods use all image data and minimize the pixel-to-pixel dissimilarities. Feature-based methods match image features, which enables the automatic detection of the correlation of images with overlapping parts. In [4] we also find an interesting definition: image stitching is the task of combining images with overlapping parts to one big image. In [5] authors alert that this technique needs a sequence of complex computation steps, especially the execution on a mobile device can take long and consume a lot of energy. In this paper, contrary to the study exposed in [4] we have used techniques of advanced computation methods in order to accelerate the computational phase and to reduce the impact of the analysis on the energy consumption.

This procedure was applied to a set of views taken from a tomato. The results of the analysis throw a percentage of affected surface.

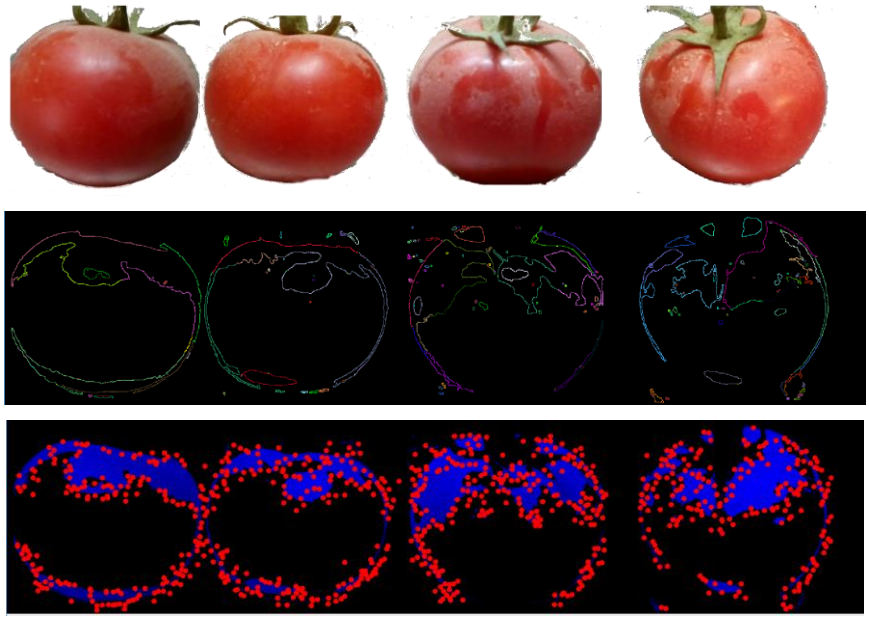

Figure 4. Image stitching and computation of the images.

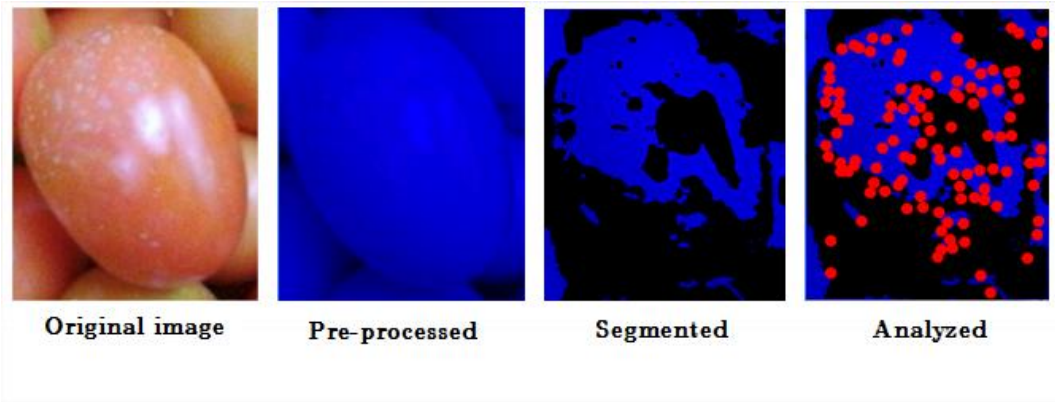
In Figure 4 different stages of the processing of the homography are shown. These stages are applied to get the percentage of the fruit with damages or dirt.

3. Implementation

This section is devoted to describe the implementation of the solution in an Android based device. We have chosen this sort of device as a sample of a embedded device that could be installed in the production lines.

To do this, let's first explain how the analysis is performed by explaining each step in the first approach, the generic algorithm. And a posteriori, we will see the variants of this generic algorithm applying parallelism to be able to improve its performance. In this case, 2 improvements have been made. The first, an improvement using Java threads (Android AsyncTasks); and the second is to use a kernel using the renderscript enhanced computing module for Android. These methods will be explained in detail later.

The stages involved in the analysis of the surface have been used in order to obtain features from the set of images; so that the percentage of damaged surface can be computed. Steps are processed sequentially.



The algorithm has four elemental stages:

- Pre-processing: the space color is moved to HSV to make it light-bright independent.
- Segmentation: helps in identifying where the interesting areas are (dirt, damages,…). A threshold is added to the processing stage to select a subsect of HSV values that are of interest for the analysis. The parameters involved are H (hue) and S (saturation).

- Analysis: in the areas of interest detected in the previous stage, points of interest are calculated (points in surface where dirt is concentrated).
- Results: pixels that fall into the segmented and analyzed areas are computed in relation with the total surface and the ratio of damage is calculated as $\%\,damage = (\#\,points * \pi * \llbracket 5\text{^}2 * 100 \rrbracket\ \text{^}\,)/surface$

4. Results

Image	Analyzed image	% dirt	Lineal (ms)	Threaded (ms)	RS (ms)
		42,78	9789	7784	5376
		41,68	11976	8734	5526
		40,74	10905	8803	5317
		42,75	11224	8373	5348
		53,65	10194	8794	5252

The lineal version processes all the stages image after image. The threaded version uses Android AsyncTasks to concurrently compute the analysis steps in each image that is added to the set of the images.

The RS or RenderScript version was implemented using the C99 standard. RenderScript is a computation module operating at native level that allows to parallelize operations on the pixels of images. RS allows to use CPU and GPU as well as associate light computational operations on pixels instead of on images. In RS each pixel is not a process or a thread, operations on pixels are grouped in computational units to be processed concurrently.

As it can be seen, the RS version shows to be faster than the threaded version. As new data is added to the homography buffer, new computation is associated with the RS kernels and new operations are concurrently started. The fine grain that is achieve shows to perform better than the threaded version.

5. Conclusions

Production lines, in agricultural processing companies, are very sensible to the conditions of the products that each producer is serving. In order to calculate and to predict the risk of each producer to the production line, tools to measure and instrument these conditions are advised. We have proposed an algorithm to compute the conditions of the product (tomato in this case) that enters in the production lines.

The study that is realized is based on image analysis. Three versions of the algorithm were tested (with single images and with homography based images). The lineal version (which was not parallelized), the threaded based version which was based in assigning a thread to a new image that was added by the device and the renderscript based which uses a model where operations per pixel are grouped obtaining a fine grain and better results.

We can conclude that it is possible to conduct these tests using conventional embedded devices and commercial operating systems like Android. Also, a method to assign costs and risks to each producer can be developed as measures on the quality and damages of the product are possible and fast.

Abstract

Robotics has established itself as one of the emerging technologies that allow us to contribute an innovative and highly meaningful methodology in all stages of education. But its implementation in Early Childhood Education has a strong potential even in its incipient phase. In the first place it allows the formation of the first spatial and temporal concepts in a playful, interactive and constructive way. At the same time, another potential of Robotics in the first educational experiences is that it enhances learning according to the different types of intelligence.

This study, which has an introductory character and seeks an approximation to Robotics and its application in Early Childhood Education has been developed with a group of children of 3 years, where Robotics is implemented for the first time with the aim of establishing the impact in learning the first spatial concepts. With this, we intend to have the starting point, to be able to complete, in a future, the evolution of these students to the learning through Robotics in a longitudinal way.
Key words: Educational Robotics, Multiple Intelligences, Early Childhood Education, Meaningful Learning

1. Introduction

The globalized world in which we live requires that from early ages the children to be immersed in the advances of the Information and Communication

Technologies (ICT) since they are undoubtedly Digital Natives. These tools allow the creation of new spaces in the classrooms to be able to approach new learning processes allowing a more meaningful knowledge acquisition as long as there is a balance between the knowledge to be transferred, the methodologies used for it and the way in which technological are applied.

There is no doubt that as teachers we have to stand out that the challenges our students need require languages and dynamics designed for them in order to introduce critical and reflexive thinking and to enhance meaningful learning and; ultimately, to teach them based on the needs with which they will have to face in the future.

The stage of Early Childhood Education is ideal given the great cerebral plasticity of children in this period. All the learning that the child is acquiring being them of a cognitive, physical, motor or communicative character evolve in an integrated way. The child establishes the foundation of his identity, his emotions and the way of deciphering the reality in which he is interacting. By age 3, children are able to associate different situations with their own experiences and at the same time relate them with the emotion they can provoke. They are aware of the existence of different mental states and they have also internalized the rules of behaviour typical of their socio-cultural environment, [1]. In short, they are able to understand and attribute meaning to a given situation, all this based on previous knowledge, expectations and curiosity of their evolutionary moment. Moreover, an aspect to keep in mind in reference to the above statement is emotional education. Backett explains that school learning should be added to the purely cognitive learning emotional education in children, since both elements contribute to an integral development of the personality.

In relation to the insertion of ICT, the TPCK (Technological Pedagogical Content Knowledge) model proposed by Mishra and Koehler [5] establishes a clear connection between Content, Pedagogy and Technology allowing the integration of technology in three Theoretical, Pedagogical and Methodological levels. A special emphasis should be placed on the fact that what is important in technology is not to use it, but to know how to use it.

In the case of Early Childhood Education, free school trends are now being widely expanded, as they allow us to stage the methodologies that are key for educational systems to evolve towards open models [6]. In this sense, ICT represents a great opportunity to work towards these more open horizons [3]. Roig-Vila studies the role that ICT plays in the key aspects of Early Childhood Education. In his study, he notes that ICT represent a great opportunity to enhance aspects such as personal initiative, as they are consultation resources and through

which methodologies can be worked based on the needs of the students. Moreover, they also help students to create their own identity by making them inquiring about those aspects that appeal to them. This is very important to work the contents not only in a globalizing way, but also specifying in each of the daily situations that can arise. He also comments that ICTs can be a great help in promoting language development in these short ages due to the use of images, videos, etc. Robotics increases students' interest and participation in STEM subjects (Science, Technology, Engineering and Mathematics) and the fact of learning to program at an early age has a positive influence on improving decision-making and solving problems skills and therefore personal autonomy based on the constructivist approach in which the student is the centre of learning [4].

In Early Childhood Education, there are few publications on educational robotics and computational thinking, and especially in which the integration between the learning process and the use of robotics can be clearly seen, [2]. However, it is a fact that Robotics is increasingly introduced in the classrooms demonstrating that it fosters aspects as necessary as creativity, autonomy, learning based on trial error, and most importantly, the fact of developing the ability of being able to identify possible solutions using certain algorithms that can be transferred to different problems. In Childhood Education the most commercialized and used robots are the Bee-Bot® and Blue-Bot® and its use is mainly based on empowering students in the process of solving a series of challenges through a sequence of actions ordered through computational programming to foster logical-mathematical intelligence.

There are several aspects related with the fact that the introduction of educational robotics can be positive in this educational level, in addition to logical-mathematical intelligence. One of them is the improvement of spatial intelligence, since it promotes the development of space-time perception, having to order actions to sequence events and to get the robot to move in a desired direction. In addition, the collaborative work that implies the use of this tool is also positive to enhance respect, tolerance, socialization, interest, motivation and self-esteem because students see how the robot is managing to do the missions that they have programmed themselves. A meaningful learning based on trial-error is earned which takes the starting point in their motivation.

2. Methodology

The methodology will include two clearly differentiated and complementary parts. We will start with a study based on qualitative methodology which will be completed with quantitative cross-cut methodology. First we are oriented to the

understanding process to describe and to interpret what Robotics is and its application in the environment of the Early Childhood Education. The technique for the collection of information consists of a deep bibliographical revision that intents to understand the dimensions of the study object and its didactic application.

Secondly, data will be collected on the response of students to their participation in the session in which Robotics has been used. The technique for collecting information will be based on an evaluative questionnaire with 15 items with a response in the form of a liker scale with values in 1-5. With this, we will be able to objectively establish the learning and / or improvement obtained in the students, as a first diagnosis, in order to have a starting point for future longitudinal monitoring.

3. Experience Description

From a didactic application point of view, we will describe this experience of learning mathematics in Early Childhood Education with a Robotic educational resource. Two main learning objectives can be achieved: a) To promote the approximation and the initial learning of mathematical aspects such as sequencing, laterality and spatial notion: front, back, side and side, etc.; b) To develop multiple intelligences through the skills of teamwork, respect, curiosity and creativity. The resource used are the BeeBots which are an educational resource to work on computational thinking and favour the directional language, turns, laterality and basic spatial concepts by directing the movement of bees. They allow beginning to teach control, directional language and programming to children from the age of 3.

The experience is located at Escola Edumar in Barcelona, endowed with a Special Education Support Unit (SESU) and in which students with a great diversity of learning levels are enrolled. The first step is always based on the teacher's description of the situation to be solved. For example the first problem is to get the Robot to advance in a straight line, stop at the end and turn the head 90º to the right, 90º to the left and put it back straight. Students should take into account three basic aspects: a) Each time a button is pressed, Bee-Bot's eyes blink and a sound confirms the instruction; b) The Robot always go forward or backwards 15 cm and turn on itself 90 °. The sequence is done step by step, marking each action with light and sound. It has a memory of 40 movements; c) The X button erases the memory to start a new sequence, otherwise it will repeat the old sequence and then the new instructions.

Taking this information into account, the different groups of 3-year-old children perform the 3 phases of the project: a) They analyse the possible alternatives of

programming the robot through the technique of manipulation; b) they choose the solution they thought to be more appropriate; c) they implement it. All this generates great motivation and involvement in the children as they participate orally, manipulatively, playfully, etc. The teaching work in these activities is none other than to help the students to reflect, anticipate, rehearse and test and then rethink about the results obtained.

4. Conclusions

The development of the first stage of this study leads us to conclude that the true digital literacy must be consolidated from the earliest stages of life. This study is based only on a first experience as a starting point and we intend to follow the evolution of these students after the use of the tool.

On the other hand, it is necessary to highlight the lack of studies on the application of Robotics focused on the stage of Early Childhood Education and for this reason it is very useful to provide objective data about it. Teachers are very motivated by the potential of Robotics.

Classroom implementation of robotics-based technologies is an opportunity to innovate in the didactic applicability and the educational approach from a global point of view, due to the fact that it contemplates the didactic, methodological, and curricular dimensions.

Solving Wave Equations on Fullerene Surfaces

James Avery[1]

[1] *Niels Bohr Institute, University of Copenhagen, Denmark*

email: avery@nbi.ku.dk

Abstract

Can we solve the electronic wave equations when there is no coordinate system?

The question arises from the wish to treat certain polyhedral carbon molecules, fullerenes and fulleroids[1,2], as two-dimensional closed surfaces. This would allow us to solve for their electronic structure on their intrinsic surface manifolds, which can be derived directly from the bond structure. The wave equation restricted to the (non-Euclidean) surface could then be solved without reference to any three-dimensional geometry of the molecule, and hence without the need for quantum chemical geometry optimization.

The resulting 2D system can potentially be solved several orders of magnitude faster than the full wave equation. But because it is a non-trivial task to find global coordinate systems for such curved surfaces, we must devise methods that can do without.

In this talk, I describe the mathematical challenges this poses, and my work in progress on solutions to overcome them.

Topological Effects in 1-Pentagon Carbon Nanocones: Migrating Faces and Magic sizes

Adhemar Bultheel[1] and Ottorino Ori[2,3]

[1] *Department of Computer Science, KU Leuven, Belgium*

Abstract

Changes in topology descriptors of one-pentagon carbon nanocones are investigated using both, direct F and dual graph F^D representations. *Topological compactness* and *topological roundness* - described by Wiener index W and topological efficiency ρ index respectively - dominate the growth of such a structure. Various chemical implications are forecasted on the basis of our purely topological model.

Key words: carbon nanocones, topological compactness, topological roundness
MSC2000: AMS Codes (none)

1. Introduction

Variations of the topological features of carbon nanocones with one pentagon at the apex (1-P NANOCONE) are investigated using both direct F and dual graph F^D representations. In this work we derived the asymptotic values for two important topological indices, the Wiener number W and the topological efficiency ρ index, improving previous numerical studies [1]. The two invariants are distance-based topological descriptors that, by taking into account the long-range structure of the graphs, describe important structural characteristics of the underlying nano-system, *i.e.* its *topological compactness* (W) and *topological roundness* (ρ).

Both indices drive the growth of such a structure when successive circles f of carbon atoms are added to it ($f \geq 0,1,2\ldots$, $f=0$ corresponding to the isolated pentagon case). When the 1-P NANOCONE is represented in the direct space (the N nodes of the graph correspond to the N carbon atoms of the chemical structure), the graph invariants follow the asymptotic curves reported in the box below.

F is made by 1 pivotal pentagon P surrounded by f concentric belts of hexagons $f = 0, 1, 2, 3, \ldots$.

Total number of hexagons is:
$n_6 = \frac{5}{2}(f^2 + f)$

Total number of faces $n_T = n_5 + n_6 = n_6 + 1$

for $f=0$ then $n_T = n_5 = 1$

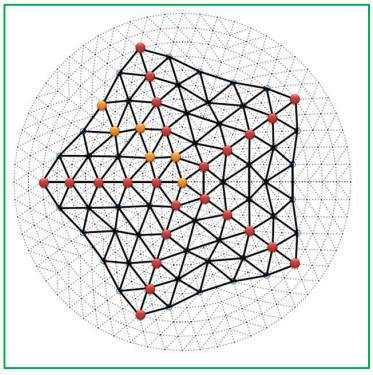
The number of nodes (carbon atoms) N obeys to the rule:
$N = 5 + 5(f^2 + 2f)$

Wiener index goes like:
$W(f) = (124f^5 + 620f^4 + 1205f^3 + 1135f^2 + 516f + 90)/6$

Other 1-P NANOCONE invariants have been derived in F and F^D.

2. Some Results

Present topological modelling is rich of original results on the chemical features of the nanocones, that are really very hard to achieve just by employing ab-initio investigations.



First of all, our topo-simulations show that the position of the most stable hexagonal face varies as a function of the nanocone size f, influencing in such a

way the stability of the whole structure (see the yellow path in the figure above). This migration follows a sequence of peculiar “jumps” in correspondence of specific *f* values.

Moreover, for certain numbers of hexagons (*magic sizes*), the conic cage results topologically more stable than graphenic fragments having similar number of atoms. Topological features make then 1-P NANOCONE suitable for generating fullerene-like structures whose presence in carbon black graphene sheets or in activated carbon has many experimental implications. The importance of fullerene-like structures also involves the interstellar carbon dust, playing in such a way a crucial role in catalyzing the formation of molecular hydrogen and other low-temperature chemical reactions.

An Ensemble Approach for *in silico* Prediction of Ames Mutagenicity

Gonzalo Cerruela García, Nicolás García-Pedrajas, Irene Luque Ruiz and Miguel Ángel Gómez-Nieto

Department for Computing and Numerical Analysis, University of Córdoba, Spain

emails: gcerruela@uco.es, npedrajas@uco.es, iluque@uco.es, mangel@uco.es

Abstract

In this paper, we propose and evaluate a method for molecular activity prediction. The proposal is based on the construction of ensembles of classifiers applying a supervised projection of the input space using Nonparametric Discriminant Analysis.

Testing these ensembles of classifiers for the *in silico* prediction of Ames mutagenicity, we have demonstrated the better behavior of our proposal with respect to classical methods.

Key words: QSAR, Ensembles of Classifiers, Mutagenicity prediction.

1 Introduction

The discovery and design of new drugs uses in vitro methods, in which laboratory experiments are performed to discover the activity of ligands with a target protein molecule. This approach is extremely expensive in terms of time and money when applied to determining activity on a large number of molecules.

Moreover, it is necessary for a drug that reaches market to possess perfect ADMET properties (absorption, distribution, metabolism, excretion, toxicity). The toxicology of drugs is a crucial research field in preclinical studies, constituting one of the leading causes of attrition in all stages of drug design.

Today, companies involved in the development of drugs lend a special interest in *in silico* prediction of toxicity to reduce time and production costs. In particular, there is great interest in the study of the mutagenic effects due to its close relationship with carcinogenicity. The most typical assay for mutagenicity is a

short-term bacterial reverse mutation assay proposed by Ames [1] that detects a large number of compounds that can induce genetic damage and frameshift mutations.

Quantitative studies of the structure-activity relationship (QSAR) using machine learning techniques is a useful *in silico* prediction method. QSAR is basically used to study biological activities with various properties associated with structures, which is useful in explaining how the structural features of a molecule influence biological activities.

Several studies have shown that it is not possible to apply a unique matching learning algorithm for QSAR applications [2]. On the contrary, in many cases, the use of combined prediction models is necessary to increase the applicability model beyond what is achievable with a single algorithm.

In the last decades, several algorithms have been used to construct QSAR models. For instance, in [3-6], the use of support vector machines (SVM) was proposed; in [7-10], models were based on decision trees, and in [11-13], the models were based on artificial neural networks.

Other authors [14, 15] proposed a combination of classifiers using an ensemble of different independent classifiers including support vector machines, decision trees, k-nearest neighbor (k-NN) and naive Bayes.

Ensemble methods are useful tools for modeling complex relationships between independent and dependent variables [16]. These methods are designed to overcome problems with single predictors and avoid over-fitting the training data [17]. Ensembles based on random subspaces of descriptors by averaging k-NN or SVM models have been constructed [18]. Though difficult to interpret, ensembles models can cope with highly nonlinear and difficult problems where simpler methods suffer from high bias due to their limited power.

Thus, in [2], different ensembles of decision trees such as boosting [19], bagging [20], and random forests [21] were compared with respect to standard classification methods. The authors concluded that a Random Forest (RF) model consistently improved classification accuracy with respect to a single tree over several QSAR applications.

The goal of this work is to extend a method to construct ensembles of classifiers [22] to the prediction of Ames mutagenicity. Our proposal is based on the use of Nonparametric Discriminant Analysis (NDA) as a linear supervised projection method used for constructing ensembles, comparing different classification methods such as C4.5, k-NN and SVM.

Also, we have devoted special attention to the chemical data used by the tested methods. Although QSAR statistical models have an acceptable predictive capacity, it is also necessary to pay attention to other necessary steps such as calculation of the molecular descriptors representing the essential information of a molecule in terms of their physicochemical properties such as constitutional,

electronic, geometric, hydrophobic, quantum, lipophilicity, solubility, and structural topology.

Several algorithms and software applications can be used to encode the chemical information in molecular descriptors, which will be used as independent variables to construct QSAR models [23-28]. In this work, we use the RDKit toolkit [28] that provides a wide range of molecular types of descriptors, including constitutional, topological, hybrid and van der Waals surface area.

The paper is organized as follows: Section 2 describes the characteristics of the benchmark dataset, and the method for constructing ensembles of classifiers; Sections 3 and 4 study the classification performance when applying ensembles with respect to standard methods and discusses the results; finally, Section 5 provides the conclusions of our work.

2 Materials and Methods

2.1 Data set and molecular representation

In order to obtain a technically feasible prediction model for mutagenicity, in [3], a clearly defined reference benchmark was proposed. This Ames mutagenicity benchmark dataset was derived from information contained in CCRIS [29], Helma et al. [30], Kazius et al. [31], Feng et al. [32] and Judson et al. [33].

The final dataset contains 6512 compounds as canonical smiles molecular representation with the corresponding Ames test results and references; this benchmark can be downloaded from [34]. The class's distribution behaves as follows: 3503 molecules correspond to the positive class and 3009 to the negative.

The predictive accuracy for the algorithms proposed in this paper was tested using the 177 descriptors generated by the RDKit toolkit software. The RDKit user manual contains a complete list of the descriptors and the corresponding bibliographic references [28].

2.2 Constructing ensembles of classifiers

In a previous work [22] the construction of ensembles projecting the input variables in a way that facilitated the accurate classification of misclassified instances without damaging the overall performance of the ensemble was proposed. This projection was implemented using the hidden layer of a multilayer perceptron [35].

That approach incorporated the advantages of boosting without its main drawbacks. The construction of the projection only accounted for instances that have been misclassified by a previous classifier, which permitted the new classifier to focus on difficult instances. However, as this classifier received a uniform distribution of the training instances, the sensitivity to noise and the effect of small datasets were greatly reduced. This method uses the whole input space reduced diversity and made the projection difficult to obtain, especially in the case of many inputs and few misclassified instances. To avoid this effect, a new method was

developed [36] in which the supervised projection uses random disjoint subspaces instead of all inputs and the neural network projection is substituted by a NDA linear supervised projection.

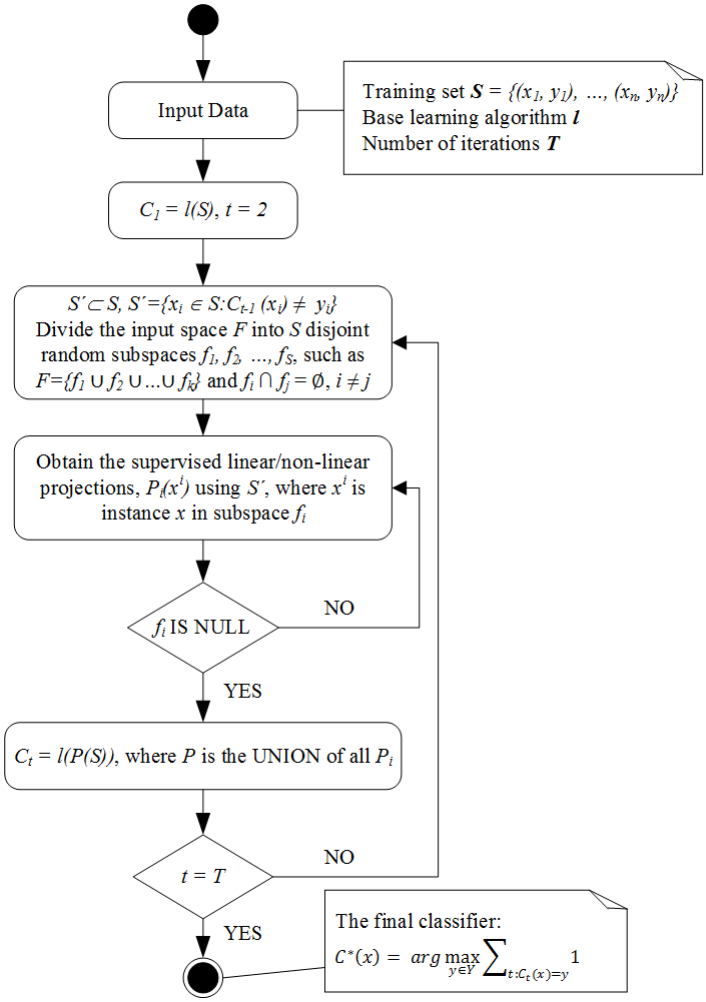

Figure 1: Algorithm for constructing the ensemble of classifiers using subspace linear/non-linear supervised projections

Figure 1 shows the proposed algorithm. At step *t*, the projection considers only the subset of instances $S' \subset S$ misclassified by the classifier added at step *t-1*. To train the classifier at step *t*, the input space is divided into several random disjoint subspaces. The instances in S' are used to obtain a supervised projection that focuses on misclassified instances. The original training set is subsequently projected using these transformations, and the next classifier is trained on these projected spaces using a uniform distribution of the instances. The projection is always performed using as inputs the original variables.

From the point of view of supervised projection algorithms, subspace projection has several advantages compared to projecting the whole input space. The algorithm is faster and more stable, as many inputs with few instances usually yield to ill-posed problems.

Our proposal is based on the use of Nonparametric Discriminant Analysis (NDA) as the linear supervised projection method. NDA is an alternative to the Linear Discriminant Analysis (LDA), which eliminates its two major problems: a) the Gaussian assumption over the class distribution in the dataset, b) limitation in dimension of the subspaces by the number of classes [37].

NDA can be formulated for the multiclass case as follows:

$$S_b^{\mathrm{NDA}} = \sum_{i=1}^{L} P_i \sum_{\substack{j=1 \\ j \neq i}}^{L} \sum_{l=1}^{n_i} \frac{w_l^{(i,j)}}{n_i} D_j\left(x_l^{(i)}\right) \cdot D_j\left(x_l^{(i)}\right)^T \tag{1}$$

$$S_w^{\mathrm{NDA}} = \sum_{i=1}^{L} P_i \sum_{l=1}^{n_i} \frac{w_l^{(i,j)}}{n_i} D_i\left(x_l^{(i)}\right) \cdot D_i\left(x_l^{(i)}\right)^T \tag{2}$$

$$w_l^{(i,j)} = \frac{min\{d\left(x_l^{(i)}, x_{\mathrm{kNN}}^{(i)}\right)^{\mathrm{p}}, d\left(x_l^{(i)}, x_{\mathrm{kNN}}^{(j)}\right)^{\mathrm{p}}\}}{d\left(x_l^{(i)}, x_{\mathrm{kNN}}^{(i)}\right)^{\mathrm{p}} + d\left(x_l^{(i)}, x_{\mathrm{kNN}}^{(j)}\right)^{\mathrm{p}}} \tag{3}$$

where p is a control parameter between zero and infinity, n_i is the number of instances in class i, p_i is the *a priori* probability of class i, $d\left(x_l^{(i)}, x_{\mathrm{kNN}}^{(j)}\right)$ is the distance from $x_l^{(i)}$ in class i to its k-th nearest neighbor in class j, and $D_j\left(x_l^{(i)}\right) = x_l^{(i)} - M_j^k\left(x_l^{(i)}\right)$ is the difference between the point $x_l^{(i)}$ and $M_j^k\left(x_l^{(i)}\right) = (1/k)\sum_{t=1}^{k} x_{\mathrm{kNN}}^{(j)}$, the mean vector of the k nearest neighbors of $x_l^{(i)}$ in class j, its "local k-NN mean".

3 Experimental setup

The experiments were conducted using a 10-fold cross-validation set-up [38]. The reported testing parameters are the average of the 10 experiments.

To evaluate the performance of the algorithms, we use accuracy (*ACC*) [39] considered as the number of successful hits compared to the total number of ratings. In the experimental results, we also included the values of sensitivity (*Sn*) defined as the fraction of positive patterns that are correctly classified and specificity (*Sp*) as the fraction of negative patterns that are correctly classified.

To the measurement of the balanced performance of a learning algorithm between these two classes, we use the *G-Mean* metric [40] as the square root of the

product of sensitivity and specificity. This measure tries to maximize accuracy in order to balance both classes at the same time.

Finally, to compare different classifiers, we use the area under the ROC curve (*AUC*) [41]. *AUC* has an important statistical property since it is equivalent to the probability that the classifier will rank a randomly chosen positive instance higher than a randomly chosen negative instance. In addition, *AUC* can be considered equivalent to the Wilcoxon test of ranks [42].

4 Experimental results

The ensembles were constructed applying the methodology described in section 2, using three different base classifiers (C4.5, k-NN, SVM). The ensembles were labeled according to the base classifier used, such as NDA-C4.5, NDA-kNN, and NDA-SVM.

All classifiers were tested for the prediction of Ames mutagenicity using the benchmark described in section 2. The 117 RDKit descriptors were used as independent variables. Moreover, the results were compared with those obtained by applying the classical methods.

Table 1: Experimental results

Method	Classical methods					Ensemble methods				
	Sp	Sn	ACC	GM	AUC	Sp	Sn	ACC	GM	AUC
C4.5	0.763	0.770	0.766	0.764	0.766	0.820	0.813	0.820	0.820	0.860
k-NN	0.784	0.773	0.779	0.778	0.834	0.823	0.773	0.800	0.800	0.864
SVM	0.770	0.824	0.795	0.796	0.865	0.832	0.810	0.820	0.814	0.873

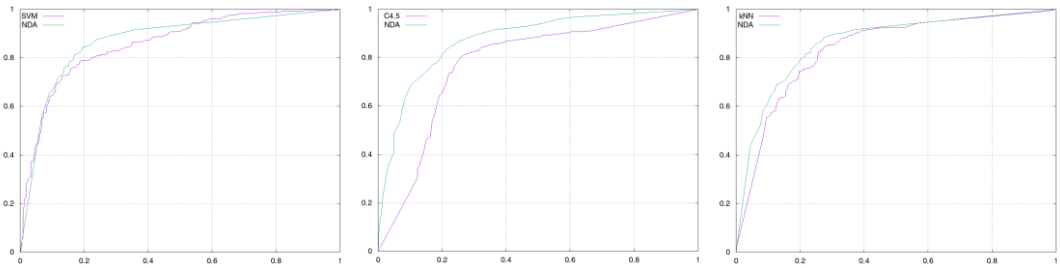
Table 1 shows the results for the standard methods C4.5, k-NN and SVM. The proportion of correctly classified instances is between 76.6% and 79.5%; the better performance was obtained when k-NN classifier was used. To better investigate the prediction ability of classifiers, Table 1 shows the values of sensitivity (*Sn*), specificity (*Sp*), G-mean (*GM*), and the area under the ROC curve (*AUC*). Regardless of the applied method, more than 76.3% of the negative patterns were correctly classified; for the case of positive patterns this value is greater than 77.0%.

As Table 1 shows the expected proportion of positives ranked before a uniformly drawn random negative (*AUC*) gets its maximum value (0.865) using the SVM classifier.

Table 1 also shows the results for the new ensembles proposed in this paper. The accuracy value obtained by the ensemble classifiers is between 2.7% to 7% higher than the standard classifiers (2.7% for k-NN, 3.14% for SVM and 7% for C4.5). In addition, the specificity is improved from 0.763 to 0.820 for C4.5, from 0.784 to 0.823 for k-NN and from 0.770 to 0.832 for SVM.

The *G-Mean* values obtained by the ensembles are around 2.83% to 7.33% higher than the standards k-NN and C4.5, respectively. A smaller increase (2.26%)

was obtained for SVM in this metric. The results for the *AUC* values showed an improvement in performance when the ensembles were used. This behavior is more marked for the ensemble based on C4.5 where an increase of the 12.2% was obtained.



(a) (b) (c)

Figure 2: ROC curves for the different models using: (a) SVM, (b) C4.5 and (c) k-NN as base classifiers.

Figure 2 shows the ROC curves for the classifiers. In all cases, the ensembles show better behavior than the standard methods. By setting an interesting area in a range of false positives between 0.2 to 0.4 (*x*-axis in the graphs), the ROC curves show good performance when SVM-NDA ensemble was used. The performance increases over the base classifier are significantly higher in this range for NDA-SVM (Fig. 2.a) and NDA-C4.5 (Fig. 2.b) with respect to the NDA-kNN (Fig. 2.c). According to these results, we concluded that the proposed ensemble is more accurate than the single classifier that makes them up.

5 Conclusions

This work evaluates new models for the prediction of mutagenicity using ensembles of classifiers constructed by applying a projection of the input variables using Nonparametric Discriminant Analysis.

The experimental results supported the advantage of the proposal compared to the application of classical methods. The greatest general improvement in the performance of the algorithm was obtained when using C4.5 and k-NN as base classifiers.

We can conclude that according to the results, the use of molecular descriptors yields good results for both the standard methods and the ensembles proposed in this paper.

In future work, we plan to extend the methods used here to evaluate the use of other linear and non-linear projections in order to further improve the accuracy in predicting QSAR methods.

3D trajectory generation for rotating extensible manipulators using zenithal gnomic projection and polar piecewise interpolants

Mihai Dupac
Department of Design and Engineering, Bournemouth University

e-mail: mdupac@bournemouth.ac.uk

Abstract

In this paper the 3D trajectory planning of the end-effector of a rotating extensible manipulator arm is described using projective geometry and polar piecewise interpolants. Perspective projections of the 3D via points located of the northern hemisphere are seen from the manipulator base location which represents the centre of rotation of the extensible manipulator. Due to the geometry of the manipulator arm, polar zenithal gnomic projections are associated with the spherical coordinates named the radial distance related to the manipulator length along the polar and azimuthal angles.
Possible trajectories of the end effector are generated using a geometric transformation applied to the polar piecewise interpolants that approximate the gnomic projective trajectory of the 3D via points. Smoothness of the polygonal trajectory is obtained through the use of piecewise interpolants with continuous derivatives between the 3D via points/nodes. The novel approach generate fast trajectory interpolation of 3D via points, minimise execution time and allows easy calculation of kinematics variables. To verify the proposed approach and to validate the model, numerical simulations are conducted for two different configurations. In this context the reachable workspace (working volume) of the extensible manipulator is examined with respect to the base location and the end effector path.

1. Introduction

Trajectory planning and control of robotic arms and manipulators represents critical key elements in industry especially when reduced production costs and improved productivity are a must [1, 2]. The ability to control the motion along a desired trajectory is imperative especially when minimal execution time [3, 4] and is considered. Moreover, optimal trajectory planning [5] require smoot trajectory generation (velocity, acceleration [11] and/or jerk) which can be achieved by the means of adequate interpolants.

Shape approximation methods and algorithms based on piecewise interpolating functions and splines [6, 7] are adequate tools in preserving positivity, monotonicity and convexity and generating smooth motion through continuous piecewise smooth functions [12] in order to reduce the induced vibrations and minimise resonant frequencies excitation. Since algebraic-trigonometric Hermite polynomials are easy to use in generating smooth and continuous motion while preserving the continuity [10], kinematic variables and joint-space trajectories can be efficiently calculated along a specified joints path. A path-planning associated methodology for a set of nodal points with kinematical requirements is presented in [9]. Quick 3D trajectory planning using cylindrical coordinates associated with the end-effector trajectory of motion is discussed in [15], an analytical approach for path planning interpolation for any industrial robot is considered in [8], and the general theory for actual kinematics and dynamics is presented in [17].

In this paper the 3D trajectory of the end-effector of a rotating extensible manipulator is generated by the use of perspective zenithal gnomic projections of the 3D via points and polar piecewise interpolants. The approach generate fast trajectory interpolation and continuous motion while minimise execution time. The proposed approach is verified by numerical simulations conducted for two different configurations. In this context the reachable workspace (working volume) of the extensible manipulator is examined with respect to the base location and the end effector path.

2. Mathematical Modelling

Manipulator Model

The rotating extensible manipulator arm is composed of a rotating *z*-Guide, a slider joint (Rigid Guide) and a sliding link as shown in Fig. 1. The z-guide of the manipulator can rotate at *O* - in the fixed Cartesian reference frame *Oxyz* – about the vertical axis *Oz*. The z-guide is connected with the slider joint guide by a rigid rod r_G which is rigidly attached to it. The slider joint can rotate relative to the z-guide about the rigid rod $r_{G..}$ The sliding link which is interconnected with the slider joint can slide in and out of the slider (Rigid Guide). The height (length) of the z-guide is l_Z, the length of the sliding joint/guide is l_G and the length of the sliding link id l_{SL}. The 3D coordinates of the end effector trajectory can be expressed using spherical coordinates (or cylindrical) coordinates by

$$\begin{cases} x = \rho \sin\varphi \cos\theta \\ y = \rho \sin\varphi \sin\theta \\ z = \rho \cos\varphi \end{cases} \overset{\Leftarrow \text{ spherical}}{\underset{\text{cylindrical} \Rightarrow}{\Leftrightarrow}} \begin{cases} x = r\cos\theta \\ y = r\sin\theta \\ z = z \end{cases} \overset{\Leftarrow \text{ cylindrtical}}{\underset{\text{Cartesian} \Rightarrow}{\Leftrightarrow}} \begin{cases} r = \rho \sin\varphi \\ \theta = \theta \\ z = \rho \cos\ \varphi \end{cases} \tag{1}$$

The end effector of the manipulator arm should move to the via-points $P_1, P_2, ..., P_k, ..., P_n$ set by the user (Fig.1).

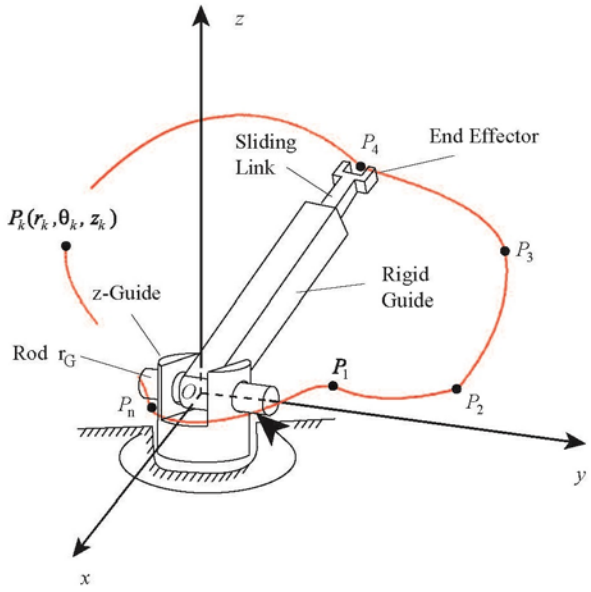

Figure 1. Rotating extensible manipulator model.

To interpolate between the data one can consider first the perspective projections of the via-points $P_i(r_i, \theta_i, \varphi_i)$ - viewed from the manipulator base location which represents the centre of projection - to a plane *N* perpendicular to the axis *Oz* and located at the distance $r_{Max} = \max\{r_i\}_{i=\overline{0,N_i}}$ from the origin *O* (tangent to the sphere of radius r_{Max} centred in origin) as shown in Fig. 2. Due to the geometry of the manipulator arm, polar zenithal gnomic projections are associated with the perspective projections denoted by $P_i'(R_i, \theta_i, \varphi_i) = P_i'(X_i, Y_i, r_{Max})$ calculated using

$$\begin{cases} \dfrac{X_i - x_O}{x_i - x_O} = \dfrac{Y_i - y_O}{y_i - y_O} = \dfrac{Z_i - z_O}{z_i - z_O} \\ Z_i = r_{Max} = \max\{r_i\}_{i=\overline{0,N_i}} \end{cases} \Leftrightarrow \begin{cases} X_i = x_O + \dfrac{x_i - x_O}{z_i - z_O}(r_{Max} - z_O) \\ Y_i = y_O + \dfrac{y_i - y_O}{z_i - z_O}(r_{Max} - z_O) \end{cases} \tag{1}$$

that is the intersection of the lines OP_i' (passing by O and $P_i, i=\overline{0,N_i}$) with the plane N. The associated radii $R_i = d(O,P'_i)$ of the points $P_i'(X_i, Y_i, r_{Max})$ - located in the projective plane N – are calculated using

$$R_i = d(O', P'_i) = \sqrt{(X_i)^2 + (Y_i)^2}$$

$$\overset{\text{Perspective Projection}}{=} \sqrt{\left(x_O + \frac{x_i - x_O}{z_i - z_O}(r_{Max} - z_O)\right)^2 + \left(y_O + \frac{y_i - y_O}{z_i - z_O}(r_{Max} - z_O)\right)^2}$$

$$\overset{\text{Gnomic Projection}}{=} \sqrt{\left(\frac{x_i}{z_i}(r_{Max})\right)^2 + \left(\frac{y_i}{z_i}(r_{Max})\right)^2} = \frac{r_i}{z_i} r_{Max} \tag{2}$$

Two projections P'_i and P'_{i+1} of the 3D via points P_i and P_{i+1} on the projective plane N are shown in Fig. 2 with the spherical coordinates named the radial distance related to the manipulator length along the polar and azimuthal angles.

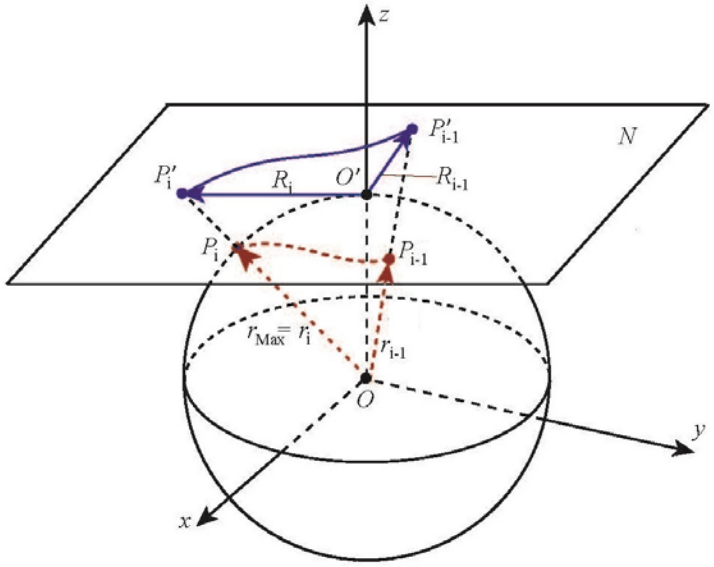

Figure 2. Perspective projections P_i' of the via-points P_i, and associated piecewise interpolation

To interpolate between the perspective projections P_i' of the via-points $P_i, i=\overline{0,N_i}$, located on the projective plane N, one can consider the angles $\theta_0 < \theta_1 < \theta_2 < ... < \theta_{N_k-1} < \theta_{N_i} = \theta_0 + 2\pi$, and the associated radii R_i. For each

interval $[\theta_i, \theta_{i+1}]_{\overline{i=0,N_i-1}}$ and associated radii R_i and R_{i+1} of two consecutive projections P'_i and P'_{i+1}, a piecewise polar interpolant that approximate the trajectory on the *projective* plane (Fig. 2) can be expressed as a Hermite-type function [13, 14] defined by

$$R(\theta) = \sum_{k=0}^{q} c_k^i (\theta - \theta_i)^k \tag{3}$$

where q is the order of the polynomial to be used (order 3 was used here), $c_0^i = R_i,\ c_1^i = \dot{R}_i, c_2^i = \frac{1}{h_i}\left[-\left(2\dot{R}_i + \dot{R}_{i+1}\right) + 3\Delta\dot{R}_i\right], c_3^i = \frac{1}{h_i^2}\left[\dot{R}_i + \dot{R}_{i+1} - 2\Delta\dot{R}_i\right],$ $R_i = R(\theta_i),\ R_{i+1} = R(\theta_{i+1}),\ h_i = \theta_{i+1} - \theta_i,\quad \Delta R_i = \frac{R_{i+1} - R_i}{h_i}$. The 3D trajectories of the end effector are calculated using the geometric transformation below

$$\begin{cases} x = \dfrac{R(\theta) z(\theta) \cos\theta}{r_M} \\ y = \dfrac{R(\theta) z(\theta) \sin\theta}{r_M} \\ z = z(\theta) \end{cases} \tag{4}$$

The trajectory height $z = z(\theta)$ for a step size S_i is approximated by

$$z(\theta) = z_i + kL_i, \qquad k = 1,2,..., N_i \tag{5}$$

where the height of a step is $L_i = \frac{|z_{i+1} - z_i|}{N_i}$ and the number of steps is $N_i = \frac{h_i}{S_i}$.

Existence of a Solution (End-Effector Trajectory)
Since the geometric path of the manipulator [7, 11] is generated using the via-points the end effector, manipulator base location and arm length, the trajectory can exist only inside the working envelope [16] defined by

$$\begin{cases} \max\limits_{P_{i_k} \in T_{P_i}} d(O, P_{i_k}) \le l_{LG} + l_{SL} \\ \max(l_{LG}, l_{SL}) \le \max\limits_{P_{i_k} \in T_{P_i}} d(O, P_{i_k}) \\ l_Z \le \sup\limits_{\overline{i=1,n;\ k=1,N_i}} (z_{i_k}) \end{cases} \tag{4}$$

where $P_{i_k}, k = \overline{1, N_i}$ represents interpolating points along the pricewise curve defined by the via-points P_i and P_{i+1}, $P_{i_1} = P_i, \forall i = \overline{1, n-1}$ and $P_{i_{N_i}} = P_{i+1}, \forall i = \overline{1, n-1}$.

1. Results

Two numerical examples are presented to illustrate trajectory generation including the existence of solutions for the extensible manipulator. The associated manipulator dimensions are: z-guide length l_z=0.5·10^{-1} m, slider length l_G = 7.5·10^{-1} m, sliding link length l_{SL} = 7.5·10^{-1} m. The z-guide is rotating with an angular velocity $\omega = 1$rad/s about the z-guide. The radial distance related to the manipulator length, and the polar and azimuthal angles of the manipulator via-points for the two chosen numerical examples are shown in Table 1 and Table 2.

Variable Name	Value									
i	1	2	3	4	5	6	7	8	9	10=1

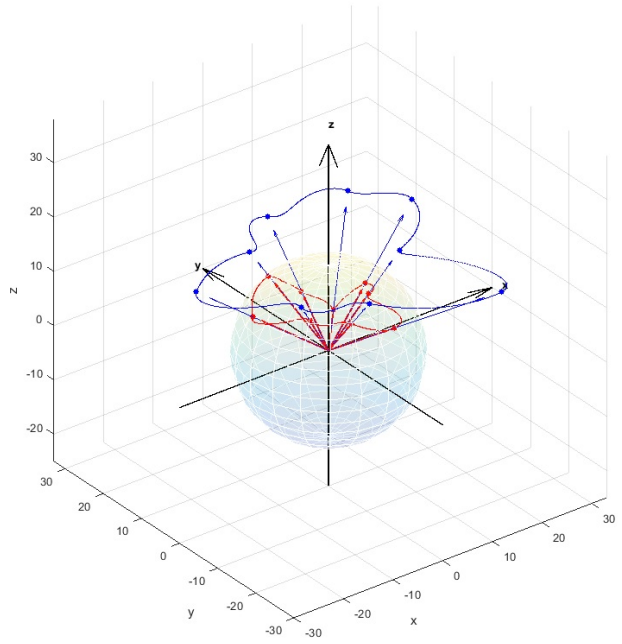
Table 1. Via-points for the 1st configuration of the manipulator (lengths in decimetres)

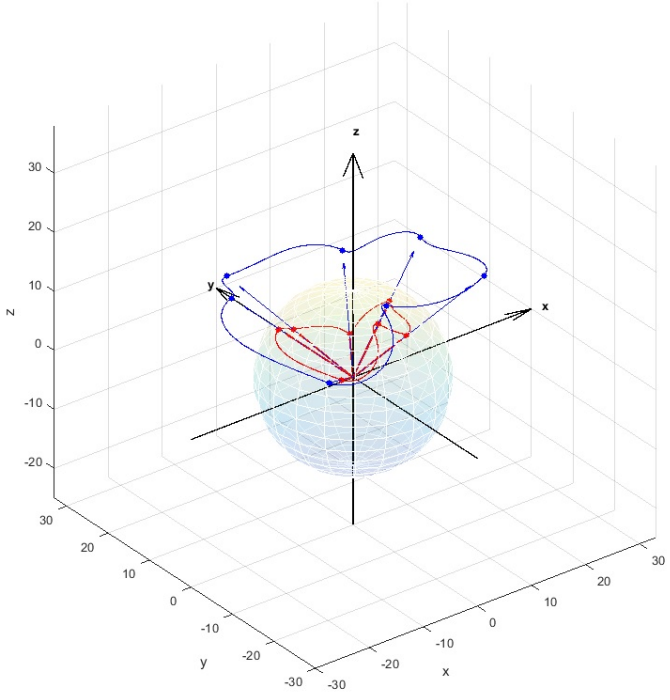
Variable Name	Value							
i	1	2	3	4	5	6	7	8=1
θ_i	20	60	130	150	225	280	335	360+20
r_i	12.8	7.8	11.4	14.2	14.8	12.0	10.0	12.8
φ_i	39	51	38	39	28	65	37	39

Table 2. Via-points for the 2nd configuration of the manipulator (lengths in decimetres)

The 3D end effector trajectory for the two manipulator configurations (Table 1 and Table 2) is shown in Fig. 3.a and Fig. 3.b. The projection of each trajectory on the *projective* plane shown in Fig. 3.a and Fig. 3.b using a blue colour – representing the radial trajectory of the end-effector in the projective plane – have been obtained using polar interpolation curves expressed as a Hermite-type functions. The red arrows pointing toward the via-points represents the radial distance related to the manipulator length in the spherical coordinates system.



(a)



(b)

Figure 3. Generated trajectory using gnomic projection and polar interpolation (a) manipulator arm goes outside the working envelope (b) end effector can reach all the via-points.

Possible trajectories of the end effector are generated using geometric transformations applied to the polar piecewise interpolants that approximate the gnomic projective trajectory of the 3D via points using the red interpolating curves shown in Fig. 3.a and Fig. 3.b. It can also be seen that the manipulator arm goes outside the working envelope/workspace [16], that is, the end effector of the manipulator arm cannot reach all the via-points in Table 1 along the planned trajectory shown in Fig. 3.a. However, for the 2nd simulation presented in Table 2, the end effector can reach all the via-points shown in Fig. 3.b.

2. Conclusions

In this paper the modelling and 3D trajectory planning of an extensible rotating manipulator end effector is presented. Polar zenithal gnomic perspective projections of the 3D via points and polar piecewise interpolants expressed as polar Hermite polynomials are considered for the end effector trajectory generations. Smoothness of the polygonal trajectory is obtained through the use of piecewise interpolants with continuous derivatives between the 3D via points/nodes. The existence of a solution in relation with the base of the manipulator arm is also addressed. Two numerical examples related to two different manipulator configurations are presented to illustrate trajectory planning and verify the proposed approach.

Abstract

In 1983, Michael proposed acceptance regions for Normal Probability Plots to detect non-normality in a set of observations. In these acceptance regions, Michael used the plotting position proposed by Hazen in 1930. In this work we have studied the influence of plotting positions on the acceptance regions in a Normal Q-Q Plot to determinate if another plotting position is better than the used by Michael.

Key words: acceptance regions, plotting position, Normal Q-Q Plot, goodness-of-fit, graphical techniques

1. Introduction

Normal Q-Q Plots are used as graphical techniques of goodness-of-fit. Confidence bands are included in a normal probability plot to detect non-normality in a set of observations with the advantage that the conclusion is not influenced by the subjectivity of the observer.

In 1983, Michael [1] proposed acceptance regions for Probability Plots using the Hazen's plotting position (1930) [2]. In this contribution we have studied the influence of the choice of plotting positions on the acceptance regions in a Normal Q-Q Plot to determinate if another plotting position is better than the definition proposed by Hazen.

2. Acceptance regions of Michael in a Normal Q-Q Plot

In 1983, Michael proposed the acceptance regions for a Normal Q-Q Plot.

Given a set of ordered observations, $x_{(1)},\ldots,x_{(n)}$, the steps to construct a Normal Q-Q Plot with acceptance regions of Michael are as follows:

1. Obtain a Normal Q-Q Plot from the observations.
2. Calculate maximum-likelihood estimators for the mean and standard deviation of observations ($\hat{\mu}$ and $\hat{\sigma}$, respectively).
3. Get the value of d_{sp}, given a fixed level of significance α and the number of observations n, in the table of critical values of the statistic D_{sp} of Michael. The value of the test statistic is calculated in the following way:

$$D_{sp} = \max_i \left| r_i - s_i \right|, \; i = 1,...,n$$

where

$$r_i = \left(\frac{2}{\pi}\right)\arcsin\left(\sqrt{p_i}\right),$$

$p_i = \dfrac{i-0.5}{n}$ is the plotting position proposed by Hazen,

$$s_i = \left(\frac{2}{\pi}\right)\arcsin\left(\sqrt{u_i}\right), \;\; u_i = \Phi\left(\frac{x_{(i)} - \hat{\mu}}{\hat{\sigma}}\right)$$

and Φ is the distribution function of the standard normal.

4. Represent acceptance regions in the Normal Q-Q Plot defined by the following expression:

$$y = \hat{\mu} + \hat{\sigma}\Phi^{-1}\left(\sin^2\left[\arcsin\left(\Phi^{1/2}\left(x\right)\right) \pm 0.5\pi d_{sp}\right]\right)$$

5. Reject the hypothesis of normality if some observation falls outside the acceptance regions.

3. Other definitions of plotting positions

In the literature there are several definitions of plotting position formula for use on Normal Q-Q Plots.

In this contribution, we are going to specify briefly nine formulae for plotting positions.

The first definition what we're going to study it was proposed by Hazen in 1930:

$$p_i = \frac{i-0.5}{n} \qquad i = 1,\ldots,n$$

In 1939, Weibull [3] proposed the definition:

$$p_i = \frac{i}{n+1} \qquad i = 1, \ldots, n$$

The third formula was introduced by Benard and Bos-Levenbach [4] in 1953 with the following expression:

$$p_i = \frac{i-0.3}{n+0.4} \qquad i = 1, \ldots, n$$

The plotting position formula more commonly use was proposed by Blom [5] in 1958:

$$p_i = \frac{i-0.375}{n+0.25} \qquad i = 1, \ldots, n$$

Tukey [6], in 1962 introduced the following definition for plotting position:

$$p_i = \frac{i-(1/3)}{n+(1/3)} \qquad i = 1, \ldots, n$$

Gringorten [7] in 1963 proposed:

$$p_i = \frac{i-0.44}{n+0.12} \qquad i = 1, \ldots, n$$

In 1978, Cunnane [8] proposed the following definition:

$$p_i = \frac{i-0.4}{n+0.2} \qquad i = 1, \ldots, n$$

Yu and Huang (2001) [9] introduced the expression:

$$p_i = \frac{i-0.326}{n+0.348} \qquad i = 1, \ldots, n$$

Finally, Lozano-Aguilera et al. (2014) [10] proposed a plotting position as the median of the *ith* order statistic from a beta distribution Beta(i, n-i+1).

4. Simulation Study

In this section we have developed a simulation study to examine the power of the acceptance regions proposed by Michael using the previously specified definitions of plotting positions.

The power of a statistical test is the probability that the test will reject the null hypothesis when the null hypothesis is false, i.e. the probability of not committing a type II error, or making a false-negative decision. The power is calculated by

fixing the probability of the type I error, i.e. the significance level, α. We have fixed the significance level at 5%.

For this study, 10000 samples of size n=10(10)100 were generated from 19 alternative distributions. Here, we will only have to include tables concerning Chi-square(10) and Normal distribution.

Table 1: Empirical power (in %) of Michael's acceptance regions to detect non-normality in a Chi-square(10) distribution for different definitions of plotting positions at significance level 5%.

n	10	20	30	40	50	60	70	80	90	100
Hazen	8.63	18.25	28.23	39.69	49.99	60.57	67.86	75.94	80.94	86.80
Weibull	11.97	20.33	23.35	31.56	36.60	44.38	50.39	59.91	65.19	73.16
BBL	6.73	14.71	21.97	31.55	40.43	50.71	57.87	67.69	72.53	80.60
Blom	6.75	15.12	23.54	33.71	43.08	54.30	61.00	70.69	75.40	82.77

YH	6.93	14.90	22.50	32.09	41.29	51.93	59.07	68.67	73.38	81.34
Lozano	6.89	14.77	22.03	31.47	40.57	51.06	58.19	67.94	72.77	80.83

Table 2: Empirical % of rejections under the null hypothesis of normality.

n	10	20	30	40	50	60	70	80	90	100
Hazen	5.16	4.56	4.79	5.21	4.94	5.13	4.93	5.36	4.66	5.49
Weibull	6.65	5.69	4.28	4.88	4.05	3.89	3.44	3.83	2.93	3.50
BBL	4.38	3.78	3.56	4.01	3.46	3.67	3.27	3.86	2.79	3.68
Blom	4.55	3.84	3.74	4.20	3.59	3.90	3.59	4.06	3.03	3.87
Tukey	4.47	3.74	3.65	4.10	3.55	3.84	3.39	4.06	2.92	3.77
Gring.	4.78	4.03	4.21	4.67	4.31	4.46	4.25	4.78	3.83	4.72
Cun.	4.68	3.85	3.88	4.43	3.94	4.15	3.86	4.39	3.55	4.35
YH	4.48	3.76	3.63	4.04	3.48	3.80	3.38	4.02	2.87	3.76
Lozano	4.45	3.73	3.57	4.00	3.40	3.68	3.28	3.91	2.78	3.66

In Table 1 we can observe that from n=30, the better power of the acceptance regions of Michael is reached using Hazen's plotting position. Similarly, Table 2 shows that in almost all sample sizes, with Hazen's plotting position will achieve results closer to the desired value (5%) than with the rest of definitions.

Abstract

ITU-T Video Coding Expert Group (VCEG) and ISO/IEC Moving Picture Expert Group (MPEG) are studying the potential need for standardization of the future video coding technology with a compression capability that significantly exceeds that of the current High Efficiency Video Coding (HEVC) standard, including its current extensions. Both groups are working together on this exploration activity in a collaboration effort known as Joint Video Exploration Team (JVET) to evaluate compression technology designs proposed by their experts in this area. This paper describes the coding features that are under coordinated test model study by the JVET, and presents a rate-distortion/complexity analysis to study their real capabilities. Experimental results show that the new model achieves 25% bitrate reduction, but at a cost of extremely high computational complexity (11×) with respect to HEVC.

Key words: HEVC, JEM, Evaluation, Computational Cost

1. Introduction

High Efficiency Video Coding (HEVC) [1] was developed in 2013 by the *Joint Collaborative Team on Video Coding* (JCT-VC) to replace H.264/*Advanced Video Coding* (AVC) standard [2], which is the most used video coding standard and has dominated digital video services in the domestic and professional markets for over ten years. In terms of rate-distortion (RD) performance, HEVC roughly

doubles the compression performance of H.264/AVC, but at a cost of extremely high computational and storage complexities during encoding [3].

The amount of daily data generated in our current interconnected society is astounding. An important amount of this data is transmitted using different video formats. According to the latest Zettabyte Cisco report [4], in 2015, 70% of all IP traffic, both business and consumer, was IP video traffic. Moreover, the trend predicts that this ratio will keep increasing with the market penetration of novel services such as video-on-demand, internet video to TV, virtual reality, 360-degree video or internet-based video surveillance, and existing services such as cloud storage and video streaming services. Moreover, the report also details how all this information will, most likely, be consumed through portable devices, with limited computation and bandwidth capabilities. It is expected that smartphone traffic will double the traffic originated by computers by 2020. Along with the increase in the amount of video information exchanged on the Internet, and the bandwidth and computational limitations of portable devices, there is an increasing demand for higher bit rates, higher video resolutions and better video quality.

This issue results in the need of a new generation of video coding techniques to increase the quality and compression rates of previous standards. Since the release of HEVC, ITU-T *Video Coding Expert Group* (VCEG) and ISO/IEC *Moving Picture Expert Group* (MPEG) have been studying the potential need for the standardization of future video coding technologies with a compression capability that significantly exceeds that of the current HEVC standard. To better coordinate this study, VCEG and MPEG created the *Joint Video Exploration Team* (JVET) as a collaboration framework. The scope of the JVET activity includes the consideration of a variety of video sources and applications. For example, sources include camera-view content, screen content, consumer generated content, virtual reality/360-degree content, and high dynamic range content, while example applications include broadcasting (with live or pre-authored content), real-time video conferencing, video chat, on-demand viewing, storage-based media replay, and surveillance with fixed or moving cameras [5][6].

These new efforts of standardization and compression enhancements are being explored and implemented by the JVET in a software test model known under the name of *Joint Exploration Test Model* (JEM) [7]. JEM represents the software model which is being used as a starting point for the next generation of video coding standards following HEVC.

As it has been the case for all past ITU-T and ISO/IEC video coding standards, in HEVC and JEM only the bitstream structure, syntax, constraints and mapping for the generation of decoded pictures are standardized. Consequently, every decoder conforming to the standard will produce the same output for a given standard

conformant bitstream. This limitation provides encoder developers with maximum freedom to optimize their implementations and explore new techniques to improve the standard. Moreover, to assist the industry community in learning how to use the standard, the standardization effort not only includes the development of a text specification document, but also the reference software source code of the encoder and decoder standard implementation. This reference software is usually used as research tool to improve the standard and explore new techniques. For the development of the rate-distortion/complexity analysis detailed in this paper, the reference software for JEM version 3.0 will be used as base encoder. This paper focuses on a comparative evaluation of the quality/computational cost of the HEVC and JEM codecs using objective measures of assessment to analyse their real capabilities. The comparison was performed using the JVET *Common Test Conditions* presented in [8].

The remainder of this paper is organized as follows. Section 2 includes some technical background of the HEVC standard. Section 3 presents the algorithm description of JEM under study, followed by the experimental results in Section 4. Finally, Section 5 concludes the paper.

2. High Efficiency Video Coding (HEVC) Standard

HEVC can be considered an evolution of the current H.264/AVC, since it maintains the same block-based hybrid approach used in all previous video compression standards. In addition, new tools have been introduced in HEVC that increase its coding efficiency compared with H.264/AVC [9].

One of the most important changes affects the picture partitioning [10]. HEVC defines a new flexible *Coding Tree Unit* (CTU) structure which is a replacement of the *Macroblocks* (MBs), 16×16 pixel blocks, used in the previous standards. With the aim of achieving an optimal adaptation to the content details, CTUs can vary from a size of 64×64 pixels, to something much smaller, as it can be subsequently partitioned into four square sub-blocks of half resolution, named *Coding Units* (CUs), with a minimum allowable size of 8×8 pixels. Therefore, a CTU can be further partitioned into four depth levels, from *d=0* for 64×64 CU to *d=3* for 8×8 CUs, having 4^d CUs in each depth level. Thus, a CU in depth level *d* can be denoted as $CU_{d,k}$ (k=0,1,.., 4^d-1), and the four sub-CUs pending on $CU_{d,k}$ are denoted as $CU_{d+1,4k+i}$ (i=0,1,.., 3). In a CTU of 64×64, it can be observed that the maximum number of available CUs is $\sum_{d=0}^{d=3} 4^d$.

HEVC increases even more the flexibility of the CTU by defining two tree structures containing new unit types: *Prediction Units* (PUs), and *Transform Units* (TUs). For intra-picture prediction, a PU uses the same 2N×2N size as for the $CU_{d,k}$ to which it belongs, allowing it to be split into four N×N PUs only for CUs at the minimum depth level. Therefore, the PU size can range from 64×64 to

4×4 pixels. For inter-picture prediction, several non-square rectangular block shapes are available in addition to the square ones, providing a total of eight different PU sizes (2N×2N, 2N×N, N×2N, N×N, 2N×nU, 2N×nD, nL×2N, nR×2N). The prediction residue obtained in each of the PUs is transformed using various TU sizes from 32×32 to 4×4. In Figure 1, an example of the partitioning is shown, depicting how a CTU is structured in a hierarchical tree where each CU branch ends in a leaf ($CU_{d,k}$) that is the root for the prediction and transform trees. Figure 2 shows the partitioning of CTU into CUs (white), PUs (green) and TUs (black) applied to the *Basketball Pass* sequence.

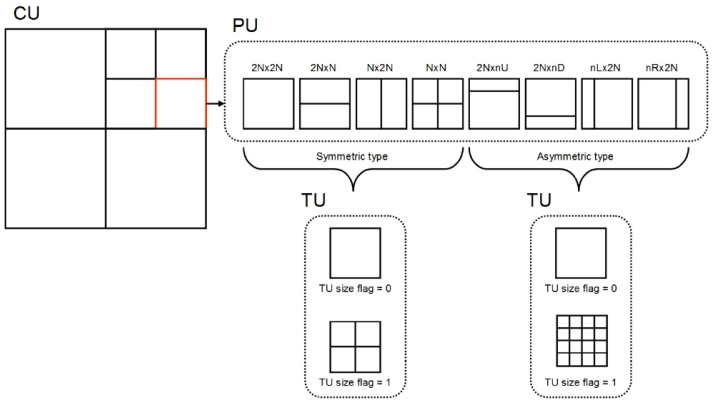

Figure 1. Partitioning of CTU into CUs, PUs and TUs

Figure 2. Partitioning of CTU into CUs (white), PUs (green) and TUs (black) applied to *Basketball Pass* sequence

It should be noted that a CTU can be split into 85 different CUs ($\sum_{d=0}^{d=3} 4^d$), which can be split into 1702 PUs, and each of these PUs has to be evaluated for all intra or inter prediction modes available, and each of the obtained residual blocks can be transformed into up to three TU sizes. HEVC checks most of the PUs (inter and intra modes) to decide whether it should split a CU or not by choosing the best

RD case. Furthermore, in the case of inter prediction, for each of these PU partitions a motion estimation algorithm is called. This wide range of possibilities makes HEVC much more computationally expensive than its predecessor, H.264/AVC. HEVC introduces changes in other modules too, such as intra prediction (where a total of 35 different coding modes can be selected), new image filters or new transform sizes [9], among others.

The above analysis evidences the need to reduce the *Rate-Distortion Optimization* (RDO) complexity for the HEVC intra/inter prediction, to make real-time HEVC video codecs with the best possible performance. With the aim of reducing this huge RDO complexity, several suboptimal fast HEVC video codecs have been developed by the industry using a reduced set of prediction modes that are previously selected as candidates, in a low complexity evaluation process.

3. Algorithm Description of Joint Exploration Test Model

This section describes the coding features that are under coordinated study by the JVET. They have been included in the JEM test model as potential enhanced video coding technology beyond the capabilities of HEVC.

JEM is being developed on top of HEVC test model (HM version 16.6) [11]. The basic encoding and decoding flowchart of HEVC is kept unchanged in JEM. However, the design elements of the most important modules, including the modules of block structure, intra and inter prediction, residue transform, loop filter and entropy coding, have been modified, introducing new tools. The following new coding features are included in JEM [7]:

- Block structure
  - Quadtree plus binary tree (QTBT) block structure
- Intra prediction improvements
  - 65 intra prediction directions
  - 4-tap interpolation filter for intra prediction
  - Boundary filter applied to other directions in addition to horizontal/vertical
  - Cross-component linear model (CCLM) prediction
  - Position dependent intra prediction combination (PDPC)
  - Adaptive reference sample smoothing
- Inter prediction improvements
  - Sub-PU level motion vector prediction
  - Locally adaptive motion vector resolution (AMVR)
  - 1/16 pel motion vector storage accuracy
  - Overlapped block motion compensation (OBMC)
  - Local illumination compensation (LIC)
  - Affine motion prediction
  - Pattern matched motion vector derivation
  - Bi-directional optical flow (BIO)
- Transform
  - Explicit multiple core transform

  - Mode dependent non-separable secondary transforms
  - Signal dependent transform (SDT)
- Adaptive loop filter (ALF)
- Enhanced CABAC design
  - Context model selection for transform coefficient levels
  - Multi-hypothesis probability estimation
  - Initialization for context models

All the methods listed above have been integrated into the main software branch of JEM [12], and in particular, in the software implementation of JEM 3.0.

3.1. Block Structure

In JEM, some additional concepts are included to this picture partitioning stage compared to HEVC. JEM incorporates a *QuadTree plus Binary Tree* (QTBT) structure for blocks. By the use of this structure, the separation in CU, PU and TU is no longer needed. This gives more flexibility for CU partition shapes to better match the local characteristics of the video sequence. Therefore, in JEM, through QTBT, CUs, TUs and PUs have the same block size. In QTBT, CUs can have either square or rectangle shapes like PUs in HEVC. Each CTU (up to 256×256 pixels) is first partitioned by a quadtree structure in squared CUs. Then, leaf nodes can be further partitioned by a binary tree structure. By the use of this tree, each CU can be split in horizontal and vertical CUs, defining the final structure of the CTU and, in consequence, its specific subdivision in CUs. An example of a CTU block structure in JEM is depicted in Figure 3. We may see how the binary tree determines the type of CU splitting. A value of 1 on the binary structure of the QTBT determines a symmetric vertical split for a CU, while a 0 value specifies a horizontal split. For the quadtree splitting, there is no need to indicate the splitting type since a block is always split horizontally and vertically into 4 sub-blocks with an equal size.

The following parameters are defined to have efficient signalling of a QTBT:

- *CTUSize*: the root node size of a quadtree, same concept as in HEVC.
- *MinQTSize*: the minimum allowed quadtree leaf node size.
- *MaxBTSize*: the maximum allowed binary tree root node size.
- *MaxBTDepth*: the maximum allowed binary tree depth.
- *MinBTSize*: the minimum allowed binary tree leaf node size.

In one example of the QTBT partitioning structure, the CTU size is set as 128×128 pixels (for the luma, and in the case of YUV420 subsampling format 64×64 pixels for the chroma), the *MinQTSize* is set to 16×16, the *MaxBTSize* is set to 64×64, the *MinBTSize* (for both width and height) is set to 4, and the *MaxBTDepth* is set to 4. The quadtree partitioning is applied to the CTU first to generate quadtree leaf nodes. The quadtree leaf nodes may have a size from 16×16 (i.e. the *MinQTSize*) to 128×128 (i.e. the *CTUSize*). If the leaf quadtree

node is 128×128, it will not be further split by the binary tree since the size exceeds the *MaxBTSize* (i.e. 64×64). Otherwise, the leaf quadtree node could be further partitioned by the binary tree. In this way, the quadtree leaf node is also the root node for the binary tree with a binary tree depth of 0. When the binary tree depth reaches *MaxBTDepth* (i.e. 4), it implies no further splitting. When the width of the binary tree node equals to *MinBTSize* (i.e. 4), it implies no further horizontal splitting. Similarly, when the height of the binary tree node equals to *MinBTSize*, it implies no further vertical splitting. The leaf nodes of the binary tree correspond to CUs that are further processed by the prediction and transform modules without any further partitioning.

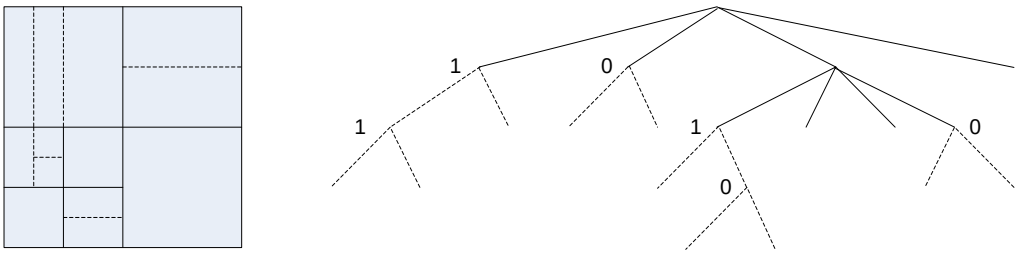

Figure 3: Illustration of a QTBT structure [7]

3.2. Intra and Inter prediction improvements

For intra prediction, to capture finer edge directions presented in natural videos, the directional intra modes are extended from 33, as defined in HEVC, to 65. The new directional modes are depicted as red dotted arrows in Figure 4. The Planar and DC modes remain the same. These denser directional intra prediction modes apply for all block sizes and both luma and chroma intra predictions. To accommodate the increased number of directional Intra modes, an Intra mode coding method with 6 *Most Probable Modes* (MPMs) is used. Two major technical aspects are involved: 1) the derivation of 6 MPMs, and 2) entropy coding of 6 MPMs and non-MPM modes.

Regarding inter prediction, with QTBT, each CU can have at most one set of motion information for each prediction direction. Two sub-CU level motion vector prediction methods are studied by splitting a large CU into sub-CUs and deriving motion information for all the sub-CUs of the large CU. *Advanced Temporal Motion Vector Prediction* (ATMVP) method allows each CU to fetch multiple sets of motion information from multiple blocks smaller than the current CU in the collocated reference picture. In the *Spatial-Temporal Motion Vector Prediction* (STMVP) method, motion vectors of the sub-CUs are derived

recursively by using the temporal motion vector predictor and spatial neighbouring motion vector. As in HEVC, JEM defines the merge mode to copy the motion information from neighbour blocks. In HEVC, motion vector accuracy is one-quarter pel (one-eighth in the case of chroma components for YUV420 video). In JEM, the accuracy for the internal motion vector storage and the merge candidate increases to one-sixteenth pel. The highest motion vector accuracy (1/16 pel) is used in motion compensation inter prediction for the CU coded with Skip/Merge mode

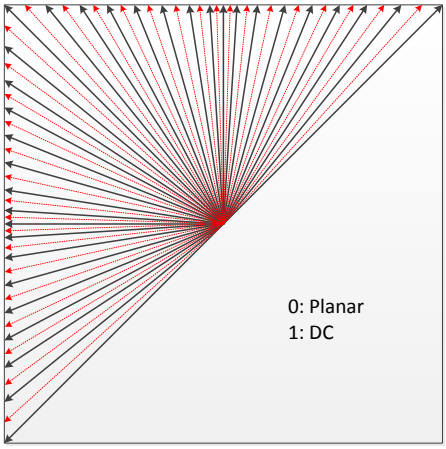

Figure 4: Proposed 67 intra prediction modes [7]

3.3. Other improvements

In JEM, in addition to the *Discrete Cosine Transform* (DCT)-II and the 4×4 *Discrete Sine Transform* (DST)-VII which have been employed in HEVC for transform coding, an *Adaptive Multiple Transform* (AMT) scheme has been chosen to encode the inter and intra residual CUs. It uses different transforms from the DCT and DST families than the ones that are used in HEVC. The newly introduced transform matrices are DST-VII, DCT-VIII, DST-I and DCT-V.

In JEM, an *Adaptive Loop Filter* (ALF) with block based filter adaption is applied. For the luma component, according to the direction and activity of local textures, one among 25 filters is selected for each 2×2 block. ALF aims to reduce visible artifacts such as ringing and blurring by reducing the mean absolute error between the original image and the reconstructed image.

In HEVC, the entropy coder used is *Context-based Adaptive Binary Arithmetic Coding* (CABAC). JEM uses an enhanced version of CABAC with a modified context modelling for transform coefficients, a multihypothesis probability estimation with context-dependent updating speed, and an adaptive initialization of models.

4. Rate-Distortion/Complexity Analysis

4.1. Encoding Parameters

This section aims to evaluate the rate-distortion/complexity capabilities of JEM version 3.0 with respect to HEVC. Our experiments rely on the default configuration of HM 16.6, which is used as an anchor for the obtained results. For a fair comparison, the experiments are conducted with a single-threaded implementation of the encoders. The hardware platform used in the experiments is composed of an Intel® Xeon® E5-2630L v3 CPU running at 1.80 GHz and 16 GB of main memory. To ensure a common framework for the simulations, the experiments were conducted under the *Common Test Conditions and Software Reference Configurations* recommended by the JVET [8] for the *All-Intra* (AI), *Low-Delay* (LD) and *Random-Access* (RA) mode configurations. That recommendation specifies the use of four *Quantization Parameter* (QPs) (22, 27, 32 and 37) and a set of 24 test sequences classified in six classes, A1, A2, A, B, C and D, which cover a wide range of resolutions from the largest (4096×2160 pixels) to the smallest (416×240 pixels), and frame rates from 100 fps to 24 fps. All the sequences use YUV420 chroma subsampling and a bit-depth of 10 (A1, A2 and A classes) and 8 bits (B to D classes).

4.2. Metrics

The rate-distortion/complexity analysis was evaluated in terms of *Encoder Time Ratio* (ETR) and R-D performance. The ETR measure was computed following the Equation (1). Regarding the R-D performance, the *Bjøntegaard Delta Rate* (BD-Rate) metric defined by ITU [14] is used. The BD-Rate provides the average difference between the R-D curves measured as a percentage of bit rate that is necessary to increase or decrease to achieve the same *Peak Signal to Noise Ratio* (PSNR) quality in both curves. In our simulation, a negative BD-Rate means the encoded bit rate using the JEM codec under study is lower than the bit rate obtained with HM, thus it is denoted as the gain in terms of bit rate saving.

$$Encoder\_Time\_Ratio = \frac{Enc.Time(JEM)}{Enc.Time(HM)} \qquad (1)$$

4.3. Simulation Results

Table 1 shows the performance progress of JEM compared with the HM 16.6 reference software for the RA configuration in terms of BD-rate gain and ETR. It can be observed that JEM codec obtains up to 26% bitrate reduction while increasing the computational complexity by around 11×. The performance of JEM 3.0 compared to the HM reference software is also summarized in terms of encoder time in Table 2 for the AI, LP-P, LD-B and RA mode configurations. A significant increase of computational complexity can be observed for the AI configuration (up to 60×).

Table 1: Comparison of different versions of JEM with HM 16.6 [13]

JEM version	Random Access (RA)	
	BD-Rate	ETR
JEM 1	-20.84 %	5.35×
JEM 2	-22.93 %	5.32×
JEM 3	-26.62 %	11.32×

Table 2: JEM3.0 compared to HEVC coding performance summary with different configurations [13]

Test configuration	BD-rate			ETR	
	Y	U	V	Enc.	Dec.
All Intra	-18%	-21%	-21%	60×	2×
Random Access	-26%	-30%	-29%	11×	10×
Low Delay-B	-21%	-25%	-26%	7×	7×
Low Delay-P	-24%	-28%	-29%	6×	4×

Figure 5 shows the profiling results of JEM 3.0 obtained for the RA configuration. These timing values have been extracted from the average of all the tested sequences and the four QP values. As can be seen, more than 70% of the encoding time is devoted to the Inter prediction, becoming the most computationally expensive operation in the encoder, whereas 23% of the total execution time corresponds to the Intra prediction. The remaining encoder modules (labelled as "Others"), including transform, quantization, entropy coding, and in-loop filtering represents only around 6% of the total encoding time. The complexity of the Inter module can be justified by the large amount of repetitive operations that the encoder has to perform on the same picture samples but with different block partitions. Finally, Table 3 shows in detail the JEM profiling results obtained for the RA configuration for all the tested sequences and for different stages of the encoder. It can be observed that the new features of "Merge" operation in JEM represent an expensive operation in the encoder.

5. Conclusions

This paper presents the coding features that are under coordinated test model study by the JVET, and presents a rate-distortion/complexity analysis. Experimental results show that the new model (JEM 3.0) achieves 25% bitrate reduction, but at a cost of an extremely high computational complexity (11×) with respect to HEVC. Future versions of the model should consider encoder complexity as one of the criteria when evaluating the new tools to be included, encouraging further encoder complexity reduction. Moreover, different techniques to accelerate the encoder should be proposed before the new standard is ready to be used in real applications. These techniques might make use of CPU and/or GPU parallelism, as well as other soft computing algorithms.

Abstract

In this paper, we propose a high parallel implementation model of an optimized version of the Mean Directional Variance algorithm using Sliding Window (MDV-SW). On the one hand, our approach allows to speed-up the HEVC (High Efficiency Video Coding) Intra-prediction in two different ways: first, reducing the total number of operations (Intra modes tested) by exploiting the directional locality of the image and, second, exploiting the parallelization opportunities to reduce the time needed for processing a block (operations involved). On the other hand, we can obtain the same perceptual information (texture orientation) from a raw video file as from a file obtained by decoding a HEVC stream. Therefore, we have focused on the real-time applications with an improved parallel version of the MDV-SW algorithm, covering most of the 33 angular directions proposed in the HEVC standard. The experimental results show that our improved version of the original MDV-SW algorithm and its parallel version can achieve a high computational complexity reduction without perceptive quality losses.

Key words: HEVC, Intra-prediction, parallel programming, OpenMP, CUDA

1. Introduction

High Efficiency Video Coding (HEVC) [1] is a new video coding standard approved by the Joint Collaborative Team Video Coding (JCT-VC) working group, from ITU (International Telecommunication Union) and ISO (International Organization for Standardization) international organizations. It is called to replace the H.264/AVC standard [2] for high resolution formats beyond High Definition (HD), such as the emerging Ultra High Definition format (UHD), known as 4K.

The high HEVC efficiency is reached through the high flexibility to adapt the three new units called Coded Units (CU), Prediction Units (PU) and Transform units (TU) to the local image features. Those units can adopt a wide range of block sizes from 4x4 to 64x64. The high computational complexity of HEVC is due to fact that the encoder must select the optimal size of the different units and also the optimal Intra-prediction mode. This process is implemented by the Rate Distortion Optimization (RDO) stage, which carries out an exhaustive evaluation of all available combinations of unit sizes and prediction modes, demanding a high computational burden.

HEVC has proved to be the state-of-the-art video coding solution for a wide range of applications, services, bit rates and formats, from the very low resolution to beyond 4K, but with an extremely high computational cost. For example, the high HEVC Intra-prediction performance is achieved by using of the brute force in the computation of the optimal angular predictor. However, that mass computing approach demands a huge amount of computation resources.

In this paper, we propose a parallel version of the MDV-SW algorithm to speed-up the HEVC Intra-prediction in two different ways: first, reducing the number of operations of the optimal gradient detection by exploiting the directional locality of the image and, second, using different parallel schemes to reduce the time needed for processing a block, trying different compilers and programming languages to fully exploit this. Hence, the MDV-SW algorithm is improved from [3]:

1. By increasing the number of texture orientations from 12 to 24 rational slopes, which improves performance and reduces the quality loss detected in the previous version. We use the Mean Directional Variance (MDV) to measure the local directionality of the image.
2. By designing a novel parallel implementation for the computation of the Mean Directional Variance.

Our approach can be used not only for HEVC encoding scenarios but also with low-power resources cameras where the video information is only available in

raw format. The explanation of the algorithm, the simulations and the performance evaluation was done with 8x8 pixels blocks.

The rest of this paper is organized as follows. Section 2 and 3 briefly introduces the scheme of the HEVC Intra-prediction, as well as the improved version of the MDV-SW algorithm, respectively. Section 4 presents the details of our parallel approach using OpenMP and CUDA schemes. Finally, Section 5 will show the experimental results. Conclusions are detailed in Section 6.

2. High Efficiency Video Coding

The HEVC standard use the well-known architecture of hybrid encoding model, where the spatial decorrelation is carried out by the Intra-prediction and the temporal decorrelation by the Inter-prediction based on the Motion Estimation and Motion Compensation (ME-MC) scheme. The residual generated by both predictions are transformed to frequential domain with the popular DCT (Discrete Cosine Transform).

HEVC has expanded the 9 Intra-prediction modes of H.264/AVC to 35 modes, covering an extremely high number of angular orientations. These modes include 33 directional modes and two non-angular modes (DC and Planar). The 33 angular modes can be classified into two categories: the first is the Integer Position Modes (IPM) composed by five modes, whose orientations match with the exact location of the reference pixels, and the second category, named Fractional Position Modes (FPM), includes the rest of the modes whose orientation is between two reference samples. Therefore, the predictor needs to be computed by the interpolation of the two nearest samples, increasing the computational cost of the process [3].

Intra-prediction follows the TUs partition tree and therefore prediction modes are applied to 4×4, 8×8, 16×16 and 32×32 size blocks. This makes the calculation of Intra-prediction stage very computationally intensive, because all of them have to be computed in order to estimate the best one between the full ranges of block size. These operations do not present any dependency among block sizes, for example 4x4 and 8x8 blocks can be calculated at the same time, but most encoders still compute the Intra-prediction using a sequential code, as the HM reference model do. The combination of data independence and computational complexity makes Intra-prediction a perfect candidate for parallelization techniques. In this article, we implemented parallelism at the block level and we evaluated the implementation on different parallel architectures to determine which one can achieve the highest Intra-prediction performance that means the minimum distortion with the minimum bit rate.

The Intra-prediction are built by using as reference samples the neighboring pixels of the left and top blocks, and these predictors have to be built in both the encoder and the decoder. However, the decoder has only the decoded pixels of the neighbor blocks that have been quantizated, and consequently their values can be far away from the original ones, depending of the quantization step used. This is the reason why the encoder is forced to use also as reference pixels the decoded pixels of the neighbor blocks, which prevents to build the predictors of one block without having been previously encoded and decoded its neighboring blocks.

3. The MDV-SW algorithm

Continuing with the work presented in [3], this work has a double aim: to improve the MDV-SW algorithm performance by doubling the number of angular prediction modes (covered in this section), and to exploit the scalability property of MDV-SW algorithm, which favors the implementation in parallel architectures.

It was proved in [3] that, when HEVC reference model is compared to the MDV-SW algorithm, the computational complexity is reduced around 30% on average, with a rate penalty of only 0.4%. This is achieved by detecting the dominant texture orientation of a block with a low complexity, which allows the selection of a reduced number of angular modes as candidates for the RDO stage.

In MDV-SW, the texture or gradient orientation of a block is given by the lowest mean directional variance along certain spatial directions (or co-lines) with rational slopes $r = r_x/r_y$, where r_x and r_y are integer positions of lattice $\Lambda \in \mathbb{Z}^2$, which is free of any pixel interpolation processing. Each pair of rational slopes (r_1 and r_2, for example) is considered to form a sublattice $\Lambda \subset \mathbb{Z}^2$, which allows the computation of the pixels belonging to the co-lines with slope r_1 and r_2. That is to say, pixels (x,y) of a co-line can be obtained from the lineal combination of r_1 and r_2, eq. (1):

$$\begin{bmatrix} x \\ y \end{bmatrix} = c_1 \begin{bmatrix} r_{x1} \\ r_{y1} \end{bmatrix} + c_2 \begin{bmatrix} r_{x2} \\ r_{y2} \end{bmatrix} + \begin{bmatrix} s_{k_x} \\ s_{k_y} \end{bmatrix} \Rightarrow \begin{matrix} x = c_1 r_{x_1} + c_2 r_{x_2} + s_{k_x} \\ y = c_1 r_{y_1} + c_2 r_{y_2} + s_{k_y} \end{matrix} \quad \forall\, c_1, c_2 \in \mathbb{Z}, \qquad (1)$$

where $s_k = [s_{kx}, s_{ky}]^T \ \forall k = 0, 1, \ldots, \det(M_\Lambda) - 1$ is a shifting vector of the sublattice Λ, which can be represented by the generator matrix $M_\Lambda = [r_1, r_2]$, as is described in [3].

As can be seen in Table I, the number of rational slopes used in this paper is 24, which is twice the number of directions proposed in [3], so we are increasing a 50% the angular accuracy of the algorithm. Figure 1 depicts the 33 angular Intra-prediction modes defined in HEVC (orange solid lines), as well as the 24 rational slopes proposed in this work (dashed blue lines for the ones used in [3], and dashed green lines for the new ones).

Table I. Rational slopes used for the texture orientation

Initial rational slopes [REF]	r_0	r_1	r_2	r_3	r_4	r_5	r_6	r_7	r_8	r_9	r_{10}	r_{11}
	-1/1	-1/2	-1/4	0	1/4	1/2	1/1	2/1	4/1	∞	-4/1	-2/1
New rational slopes	r_{12}	r_{13}	r_{14}	r_{15}	r_{16}	r_{17}	r_{18}	r_{19}	r_{20}	r_{21}	r_{22}	r_{23}
	-3/4	-2/3	-1/3	1/3	2/3	3/4	4/3	3/2	3/1	-3/1	-3/2	-4/3

By using 24 directions instead of 12, the texture orientation detection is significantly improved, since it achieves a gradient direction closer to the real dominant texture orientation of the block under evaluation. As seen in Figure 1, most of the rational slopes are either overlapping the Intra-prediction angular modes or they are placed next to them. Therefore, the MDV-SW algorithm is improved and it can be considered as good a predictor of the optimal Intra-prediction mode as HEVC.

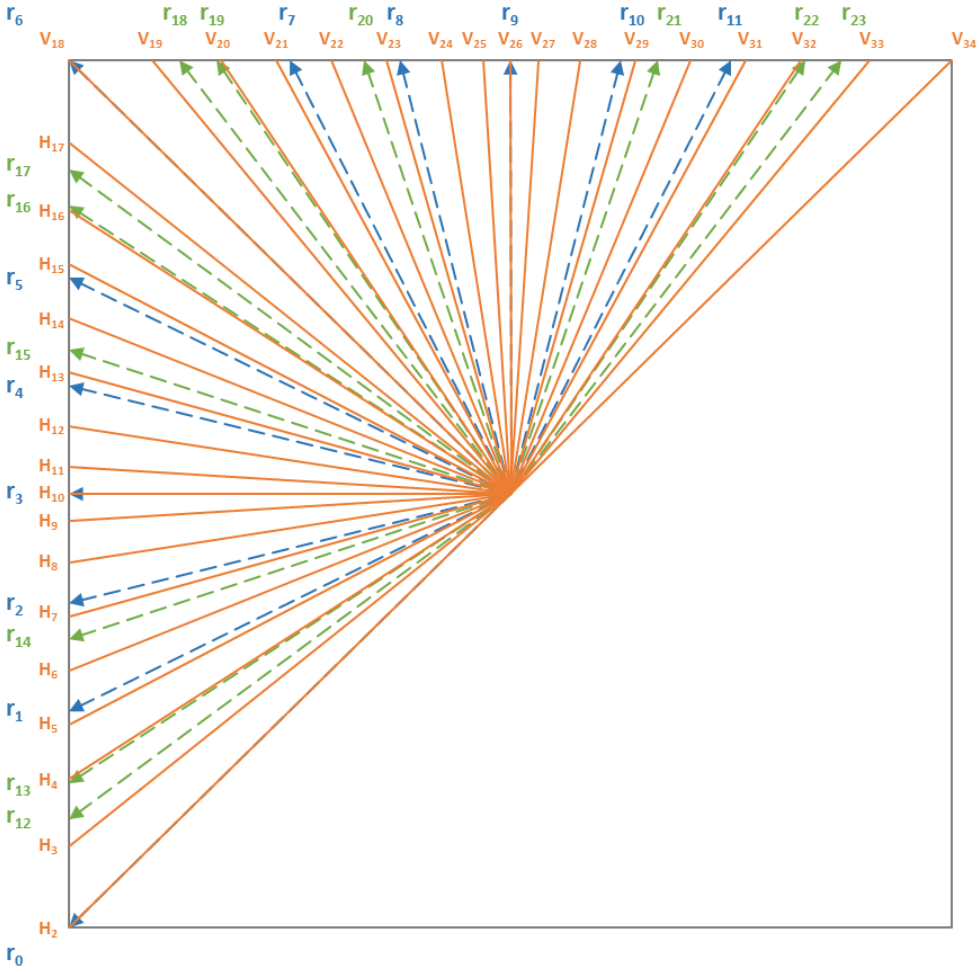

Figure 1. The 33 angular Intra-prediction modes of HEVC (solid orange lines), rational slopes used in [3] (dashed blue lines), and rational slopes added to the previous ones (dashed green lines)

In this paper, we use a block size of 8x8 pixel, which means that the MDV-SW algorithm uses 9x9 blocks, as depicted in Figure 2, where the pixels of the left-column and top-row are the reference pixels from adjacent blocks that have already been coded and decoded. In [3] it was revealed that the use of the original pixel, that means, the non-distorted pixels by the quantization stage, causes a poor orientation detection accuracy.

For each rational slope, there is a set of co-lines, as it can be seen in Table II, which are used to compute the directional variance by applying eq. (2), where $p_j(r_i,n)$ are pixels belonging to the co-line $CL(r_i,n)$, and N is the number of pixels of the n co-line with slope r_i:

$$\sigma^2[CL(r_i,n)] = \frac{1}{N}\left(\sum_{j=0}^{N-1} P_j^2(r_i,n) - \frac{1}{N}\left(\sum_{j=0}^{N-1} P_j(r_i,n)\right)^2\right) \quad \forall n \epsilon \mathbb{Z} \qquad (2)$$

The directional variance values obtained in eq. (2) are then used in eq. (3), which computes the mean directional variance for each set of co-lines with the same rational slope.

$$MDV(PU, r_i) = \frac{1}{L}\sum_{n=1}^{L} \sigma^2[CL(r_i,n)] \qquad (3)$$

The result obtained when the MDV-SW algorithm is used can be seen in Figure 3, which shows the dominant direction of the blocks selected in the synthetic image analyzed.

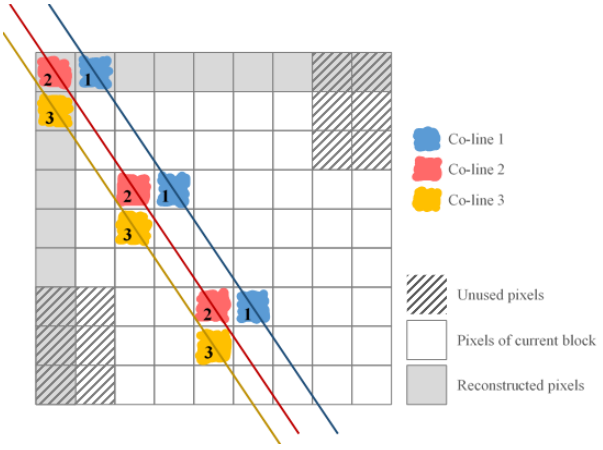

Figure 2. Example of co-lines with slope r_{19} in a 9x9 pixel block

Table II. Co-lines of a 9x9 block

Rational slopes	Number of pixel of each co-line (N)	Number of co-lines (L)
r_0, r_6	2,3,4,5,6,7,8,9,8,7,6,5,4,3,2	15
r_1, r_5, r_7, r_{11}	2,2,3,3,4,4,5,4,5,4,5,4,5,4,5,4,4,3,3,2,2	21
r_2, r_4, r_8, r_{10}	2,2,2,2,3,2,2,2,3,2,2,2,3,2,2,2,3,2,2,2,3,2,2,2,3,2,2,2,3,2,2,2,2	33
r_3, r_9	9,9,9,9,9,9,9,9,9	9
r_{12}, r_{17}, r_{18}, r_{23}	2,2,2,2,2,2,2,2,2,3,2,2,2,3,2,2,2,3,2,2,2,2,2,2,2,2,2	27
r_{13}, r_{16}, r_{19}, r_{22}	2,2,2,2,2,3,2,3,3,3,3,3,3,3,3,3,3,3,3,2,3,2,2,2,2,2	27

4. Parallel implementation

In this section, we are going to detail how the MDV-SW algorithm is implemented to be executed over different parallel architectures.

Block level parallelism

For every block of size NxN in the frame, we need to calculate 24 different gradient directions. So, the algorithm can be summarized as detailed in Figure 4.

```
forEach direction[1-24]
//The number of diagonals for each direction varies with the angle
//The next forEach example is for the rational slopes r1, r5, r7 and r11
   forEach diagonal[1-21]
      //calculate diagonal lines
      find all pixels that belong to the diagonal (Figure 2)
      add all the pixels inside the diagonal ->diagN
      calculate the mean for the pixels in the diagonal mean->diagN/npixels
      calculate the standard deviation of pixels in the diagonal (Equation 1)
    //average per gradient direction
    average[direction]=sum[diagonals]/num_diagonals (Equation 2)
 //calculate the minimum of the 21 directions
 IntraPred[BlockN]= min(average[direction])
```

Figure 4. Pseudocode

The MDV-SW direction mode for the entire block is therefore the direction that gives the minimal average. For a fixed 8x8 block size, this results in an average of 24x24=576 gradient direction calculations (24.5 is a mean value, because not all the rational slopes have the same number of diagonals). Since we have four different block sizes (4x4, 8x8, 16x16 and 32x32) in total, if we assume that the average number of diagonals is 24 for all of them, we will need 4 x 576 = 2304 gradient directions calculation (this is an estimated value, as the number of diagonals depend on the size of the blocks); the directions do not present any dependency among each other and can be calculated in parallel. In addition, we are decoding HD video where every frame contains 14399 blocks of size 8x8 and there are 30 frames per second in video, which means that for a 1 minute of encoded video we need to calculate the Intra-prediction for around 30 million blocks. Any improvement in execution time of the encoder is clearly hugely beneficial.

We chose to assign one thread per gradient line calculation which results in 24x24, 576 threads for an 8x8 blocks and a total of 2304 threads to calculate all blocks sizes. Every thread performs around 17 operations (multiplications and additions); this will lead to low computations done per thread. Part of the article purpose was to determine if the use of a multicore architecture, like Intel's Xeon [4], would be better than a many-core architecture, like the Nvidia GPUs [5]. We decided to use OpenMP [6] to program a multicore Intel's Xeon E5 architecture, using a standard open source compiler like gcc [7], and also an Intel's proprietary compiler, the Intel Parallel Studio icc [8]. We also used two different compilers to evaluate the many-core architecture: Nvidia's nvcc compiler, which requires the algorithm to be implemented using the low-level programming language/API called CUDA C [9], and the OpenACC [10] compiler, which is not proprietary, supports multiple GPU platforms and is pragma based high-level programming language. In the next section, we explain the different implementations over these architectures.

CPU multicore acceleration using OpenMP

Intel's Xeon E5 family is a multicore CPU architecture with 12 cores and HyperThreading, allowing a maximum of 24 threads of simultaneous execution. Intel's recommend the use of their proprietary C compiler, icc, to optimize the hardware specifically for fully exploiting vectorization and data alignment. The primary advantages of the Xeon CPUs are their multi-socket capabilities, higher core counts, larger cache memory, and support for ECC memory. A Xeon Phi co-processor, or co-processors, can be used alongside an existing Intel Xeon processor to provide increased/improved computing power. The architecture also allows the use of common parallel programming languages OpenMP.

Since most multicore architectures commercially available have around 4-12 cores per thread, it does not make any sense to run 504 threads on them because it will only slow the execution time. So, we decided to run 24 threads and let the compiler choose dynamically (by using the pragma schedule) how many operations we want to perform per thread. The main areas accelerated by OpenMP pragmas are:

1. `#pragma omp task`, to calculate the different blocks directions
2. `#pragma omp`, for on the one outside loop in *Figure C*.

a.1 Using gcc compiler
Compiler command and flags: **gcc -g -Wall -03 sourcefilename -fopenmp**
a.2 Using icc compiler
Compiler command and flags: **icc -g -Wall -03 -vec-report=3 -align sourcefile –qopenmp**

GPU Many-core implementation using CUDA C and OpenACC

Nvidia GPUs is a many-core architecture used in modern computers as a coprocessor to specifically accelerate graphics (video and image). Programming for these heterogeneous computer systems has been an area of research for many years to accelerate scientific computations. Since the threads used by these architectures are mostly hardware managed, the creation of the thread is basically free and their parallelism model is based on the assumption that you can run hundreds of thousands of threads in parallel. The performing improvements provided by this architecture on many different scientific computations resulted in the development of several low-level APIs (CUDA, OPENCL, etc.). Programming these APIs can take time and usually requires some level of expertise to implement them. To solve this problem, recent approaches employ directive-based high-level programming like OpenACC. OpenACC is a pragma directive based programming language designed to allow easy development for a variety of hardware accelerators, including GPUs from different vendors, multicore architectures and FPGAs. The goal of the OpenACC compiler is to improve the execution time of existing code written in Fortran, C or C++, by adding different pragma directives to the code that will allow it to run on the available accelerator. OpenACC allows programmers to quickly develop new architectures without the need to understand much of the hardware or the need to learn new vendor specific programming languages. However, since the compiler will take most of the decisions, the performance speed is usually lower than the one that can be by using from hardware specific programming languages and compilers. OpenACC support is provided by a number of vendors and is defined by an open standard.

Since we can run “many” threads in a GPU, initially we chose to calculate a diagonal per thread. However, each line is at maximum nine additions (r_3 and r_9), so the work done per thread was very low and we decided to perform two diagonals from same direction per thread.

CUDA C

Each CUDA block calculates one direction. This way, we can copy the block into shared memory reducing the global memory bandwidth bottleneck. Each thread inside the CUDA block calculates two of the diagonals. We cannot optimize for divergence, since each direction requires different pixels in the block and the calculations are slightly different - each thread performs two line and lines differ in size. The average of the standard deviations is performed as a reduction to avoid atomic adds and obtain maximum thread parallelism.

Compiler command and flags: **nvcc -arch=sm_55 sourcefile.cu**

OpenACC

The implementation in OpenACC is based on the C implementation and mainly consists in substituting the OpenMP pragmas described in a.1 by openACC pragmas. The for loops in the Intra-prediction are perfect to be accelerated by OpenACC directives, !$acc for or !$acc kernels. We added !$acc data specific pragmas to specifically express if used data should be copy on the GPU and remain there; this way we improve the communication bottleneck.

Compiler command and flags: **pgcc -acc -ta:nvidia:managed -Minfo=accel sourcefile.c**

Analysing the compiler output we can notice that the number of threads created by the GPU is below 400, which confirms that is beneficial to perform more than one diagonal calculation per thread.

5. Simulation results

If we compare the timings presented in Figure 5 for a block size of 8x8, the CUDA implementation is clearly the best one. We expect the CUDA implementation to perform even better if the video encoded is 4K instead of HD; and even more if instead of doing block level parallelism we do parallelism at the Image Level calculating all blocks Intra directions at the same time.

We find also very interesting the developing time taken to implement each solution. The summary of the lines of codes written for each implementation are presented in Table III. The solution using CUDA is the most complex one to develop. The solution in OpenACC just took around 1 hour to develop, since the code was based in a C implementation. We do expect to have a performance overhead when going from a low-level API to a high-level pragma based API, but the results are competitive and if development time or lack of a GPU

programming experts is a constrain it is a very viable option for scientists to try use GPU with OpenACC.

The multicore implementation also shows very good improvements over the sequential implementation, which means that even if accelerators like GPUs are not available, video encoding can easily be speed up without much rewriting of code, just by adding very common pragmas directives.

Table III. Lines of code needed to program for the specific compiler/ Programming language

Compiler + Library	Number of lines of code added
C (original code)	1000
C + OpenMP	4 extra line more than the original code
C + OpenACC	2 extra lines more than original code
CUDA	Complete rewrite of original code 1000. Uses Shared memory and reduction

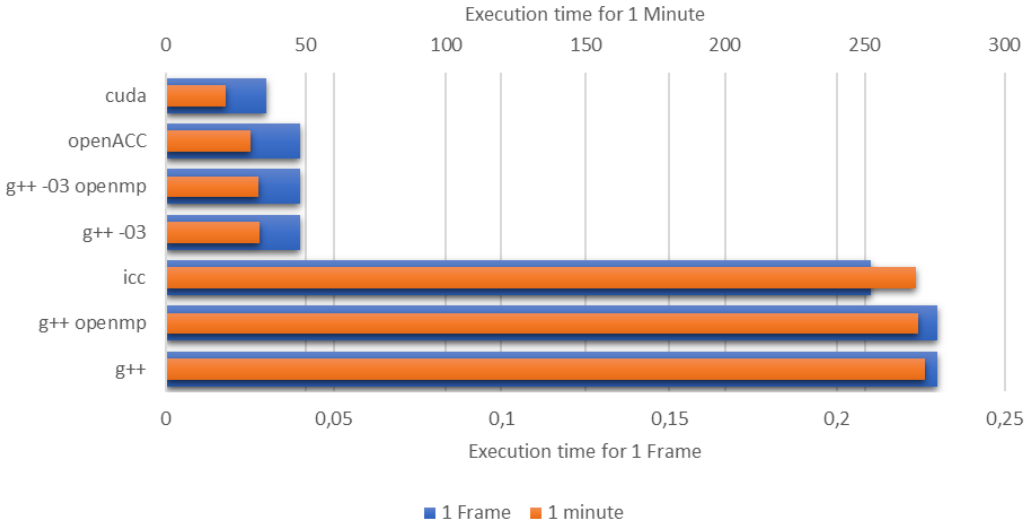

Figure 5. Execution times with parallel implementation, using an 8x8 block size

6. Conclusions

In this paper, we have presented an improved and parallel version of the MDV-SW algorithm, which is based on the dominant gradient detection. The experimental results proved that, even if the MDV-SW algorithm is not implemented within the HEVC reference software, it can be easily implemented to process raw video files over parallel architectures and obtain the texture orientation. Our approach obtained a very significant computational complexity reduction with no quality losses from a perceptual point-of-view. The MDV-SW

algorithm could also be used in a HEVC encoder scenario, since it reduces the number of Intra-prediction modes to be tested by a HEVC encoder.

Block level parallelism achieves a significant improvement over sequential execution. We did evaluate different architectures and programming paradigms to provide the optimal solution for different situations. Therefore, it will allow us to develop hardware/software systems to implement the MDV-SW algorithm focused in low-power and consumption devices.

We leave for future work how to solve the dependencies between prediction blocks in order to make the parallel implementation at Image Level possible.

Augmenting Complex Networked Systems under Improved Pinning Controllability Condition

Mahdi Jalili
School of Engineering, RMIT University, Melbourne, Australia

email: mahdi.jalili@rmit.edu.au

Abstract

In this paper we introduce a method for efficient augmentation of networked systems provided that the pinning controllability of the final network is improved. The problem is how to connect a sub-network to an already existing network such that the controllability is maximised. We consider the eigenratio of the augmented Laplacian matrix as a pinning controllability metric, and use graph perturbation theory to approximate influence of edge addition on the eigenratio. The resulting metric can be efficiently used to find the links connecting two disjoint networks. We also provide numerical simulations on synthetic networks and show that the proposed method is more effective than heuristics such as connecting nodes with high degrees or betweenness centrality values.

Key words: complex networks, pinning controllability, network augmentation, scale-free networks, small-world networks

1. Introduction

Many natural and man-made systems can be modelled as networks where a number of individual entities, known as agents, nodes or vertices, are coupled through connecting links. Real networks have been shown to share some common structural properties such as community structure, densification, power-law degree distribution and small-world property [1]. There is overwhelming interest to study various dynamical phenomena on complex networks. Examples include synchronisation [2], consensus [3], information propagation [4] and cascaded failures [5]. Synchronisation is the most well-known collective behaviour studied in networked systems, where a number of individual dynamical systems coordinate their motion through a connection graph. It has been shown that

structure of the connection graph has a major role in determining its synchronisation properties [6].

In some applications one needs to control dynamics of a networked system to a specific set point. Although dynamical networks can synchronise without presence of an external input, one can speed up the synchronisation by controlling some of the nodes. This is referred to as pinning control (or pinning synchronisation) in the literature, where external input is fed into (often) small fraction of nodes, known as driver nodes, to direct the dynamics of the whole network into a reference state [7, 8]. A number of approaches have been proposed to measure pinning controllability of networked systems. Eigenratio of the augmented Laplacian matrix of the connection graph in as effective metric measuring pinning controllability of networks [8-10]. This method is based on the assumption of having the same dynamics for the reference state and individual nodes.

Engineering network structure to have optimal levels of pinning controllability is important in many applications for which the connections graph is required to have high controllability. A number of methods have been proposed to improve pinning controllability of networks. For example, one can employ link weighting [11] or efficient rewirings [12] to enhance the pinning controllability. Another important issue in this field is to determine the best drivers. Controlling a node involves significant cost, and one is often required to achieve the control task with minimum number of drivers, or the best drivers if their number is fixed. The pinning control with best drivers has been modelled as an optimisation problem and evolutionary optimisation methods have been used to solve the problem to obtain the list of best drivers [9, 13]. Moradi Amani et al. proposed a simple metric based on the eigenvectors of the Laplacian matrix to find the most influential nodes for pinning control [14].

In this paper, we propose an approach for effective augmentation of complex networks under improved pinning controllability conditions. Network augmentation is a phenomenon with significant engineering applications [15]. For example, when a new suburb is added to the energy grid, the question is how to create the connections between the two networks provided that a certain utility function is maximised. Here we consider the case when a new sub-network is added to an already existing networked with known driver nodes. The question is how to create inter-network links between these two networks such that high level of pinning controllability is obtained in the final network.

2. Pinning Controllability of Complex Dynamical Networked Systems

Here we consider coupled identical dynamical systems where all individual nodes follow the same dynamics. Let's consider a network with N nodes, all having the

same dynamics. When there is no pinning control, the dynamics of the motion of coupled systems reads

$$\frac{d\boldsymbol{x}_i}{dt} = F(\boldsymbol{x}_i) + \sigma \sum_{j=1}^{N} a_{ij} H\left(\boldsymbol{x}_i - \boldsymbol{x}_j\right) \quad ; \quad i = 1, 2, ..., N \,, \tag{1}$$

where $\boldsymbol{x}_i \in R^d$ are d-dimensional state vectors, $F: R^d \to R^d$ defines the (uniforms) dynamics of each node, σ is a coupling strength and H is a projection matrix indicating from which dimensions the individual dynamical systems are coupled to one another. $A = (a_{ij})$ is the adjacency matrix determining the connection graph; $a_{ij} = a_{ji} = 1$ when there is a link between nodes i and j, and $a_{ij} = a_{ji} = 0$ otherwise. We suppose that there are no self-loops in the network, i.e., $a_{ii} = 0$. One can rewrite the above equation as

$$\frac{d\boldsymbol{x}_i}{dt} = F(\boldsymbol{x}_i) - \sigma \sum_{j=1}^{N} l_{ij} H \boldsymbol{x}_j \quad ; \quad i = 1, 2, ..., N \,, \tag{2}$$

where $L = (l_{ij})$ is Laplacian matrix of the connection graph; $l_{ij} = -a_{ij}$ for $i \neq j$, and $l_{ii} = k_i$, where k_i is degree of node i, which is calculated by summing all connections pointing to this node.

In pinning control (or synchronisation), often small fraction of nodes are considered as drivers to which the external control input is fed. The final aim of pinning control is to force the individual dynamical units to follow a reference state. Let's suppose that the reference state $s(t)$ has the same dynamics as the individual dynamical nodes

$$\frac{d\boldsymbol{s}(t)}{dt} = F\left(\boldsymbol{s}(t)\right) \,. \tag{3}$$

If the difference between the trajectories of the individual unites and the above reference state goes to zero as time goes to infinity, one can argue that global pinning synchronisation is obtained. To achieve this, one needs to apply the following control input to driver i

$$u_i = \sigma \beta_i k_i \left(\boldsymbol{x}_i - \boldsymbol{s}\right) \,. \tag{4}$$

where k_i is the feedback control gain, and β_i indicates the driver nodes such that $\beta_i = 1$, if node i is a driver node, and $\beta_i = 0$ otherwise. Therefore, equations of motion of the controlled networked system read

$$\frac{d\boldsymbol{x}_i}{dt} = F(\boldsymbol{x}_i) - \sigma \sum_{j=1}^{N} l_{ij} H \boldsymbol{x}_j - \sigma \beta_i k_i (\boldsymbol{s} - \boldsymbol{x}_i) \quad ; \quad i = 1, 2, ..., N \ , \qquad (5)$$

An important problem in designing pinning control strategy is to determine the parameters that guarantee stability of the synchronised solution $\boldsymbol{x}_1(t) = \boldsymbol{x}_2(t) = \ldots = \boldsymbol{x}_N(t) = \boldsymbol{s}(t)$. A number of approaches have been proposed to obtain sufficient or necessary conditions for the stability of synchronised solution in pinning control. The approach based on master stability function is a prime choice in this field [8, 12, 13, 16], which is based on studying linear stability of variational equations. It leads to a criterion for linear stability of the synchronised solution, i.e., a necessary stability condition. This solution is based on the eigen-decomposition of the augmented Laplacian matrix, defined as

$$L_a = \begin{pmatrix} l_{11} + k_1\beta_1 & l_{12} & \ldots & l_{1N} \\ l_{21} & l_{11} + k_1\beta_2 & \ldots & l_{2N} \\ \vdots & \vdots & \ldots & \vdots \\ l_{N1} & l_{N2} & \ldots & l_{NN} + k_N\beta_N \end{pmatrix}. \qquad (6)$$

The augmented Laplacian matrix is indeed the original Laplacian matrix (for the case without any pinning control input) with added diagonal terms associated with the pinning control. It has been shown that the eigenvalues of the augmented Laplacian matrix are non-zero and positive as $0 < \lambda_1 \leq \lambda_2 \leq \ldots \leq \lambda_N$ for connected networks. The eigenratio $R = \lambda_N / \lambda_1$ is considered as a metric measuring the pinning controllability such that the smaller the eigenratio R is, the better the pinning controllability is. Indeed this metric is based on the interpretation that "network N_1 is more controllable than network N_2, if for a larger range of coupling parameter σ it is possible to control N_1 as compared to N_2" [12]. An interesting thing about the eigenratio is that is depends solely on the structure of the connection graph and is independent of dynamics of individual dynamical systems.

3. Effective Network Augmentation under Optimal Controllability Condition

Our problem here is how to efficiently augment networks improving their pinning controllability. We assume that there is an existing network with fixed topology and predetermined driver nodes; let's denote this network by N_A. We then consider a new sub-network, denoted by N_B, which is required to be connected to

N_A. There will be I inter-network connections to be made between the two networks. The problem is to find the tipping nodes from N_A and N_B such as that creating I inter-network links between them results in high levels of pinning controllability as measured by the eigenratio of the augmented Laplacian of the whole network. Here we use graph perturbation theory [12, 17] in order to find an approximate solution to this problem, and show that it is more effective than heuristics such as connecting high-degree nodes from both sides.

Let's denote the eigenvalues and eigenvectors of the augmented Laplacian L_A by λ_i and $\boldsymbol{u}_i$, respectively. Let's suppose that adding an edge results in the changes in L_A, λ and $\boldsymbol{u}$ as ΔL_A, $\Delta\lambda$ and $\Delta\boldsymbol{u}$, respectively. Considering the basic definition of eigen-decomposition problem and some simple operations, one obtains

$$\Delta\lambda_i = \frac{\boldsymbol{u}_i^T \Delta L \boldsymbol{u}_i}{\boldsymbol{u}_i^T \boldsymbol{u}_i} \quad , \quad i = 1, 2, ..., N \, . \tag{7}$$

The pinning controllability index depends on λ_1 and λ_N. If a link is created between two non-connected nodes i and j, it is simple to show that the change in these eigenvalues due to this link addition can be approximated as

$$\begin{cases} \Delta\lambda_1 \approx (\boldsymbol{u}_{1i} - \boldsymbol{u}_{1j})^2 \\ \Delta\lambda_N \approx (\boldsymbol{u}_{Ni} - \boldsymbol{u}_{Nj})^2 \end{cases}, \tag{8}$$

where $\boldsymbol{u}_{1i}$ and $\boldsymbol{u}_{Ni}$ are the i-th entry of the eigenvectors corresponding to λ_2 and λ_N, respectively. Using equation (8) and assuming $\Delta\lambda_1 << \lambda_1$, the change in the eigenratio R by adding a link between nodes i and j can be approximated as

$$\Delta R \approx \frac{\lambda_1 (\boldsymbol{u}_{Ni} - \boldsymbol{u}_{Nj})^2 - \lambda_N (\boldsymbol{u}_{1i} - \boldsymbol{u}_{1j})^2}{\lambda_1^2} \, . \tag{9}$$

The above equation is the key equation to use here. One can first create a random link between networks N_A and N_B to make them a connected network, provided that networks N_A and N_B are connected networks themselves. Then, one should make an eigen-decomposition and obtain the above value for any inter-network links. Finally, the top-I values are selected and inter-networks are created based on them. Note that one has to remove the link initially created between the two networks.

4. Numerical Simulations

In order to show the effectiveness of the proposed method, we include numerical simulations on synthetic networks. As network structures for both networks N_A and N_B, we considered scale-free networks constructed as follow. First, an all-to-all connected network with m nodes is considered. Then, at each step a new node is added to the network and creates m connections. The probability that an old node is connected to the newly added node is proportional to its degree; the higher the degree of an old node is, the higher the probability of being connected to the new node. The networks evolved using this algorithm will have scale-free degree distribution, meaning that many nodes will have small degrees, while a few nodes will have large degree values. Furthermore, the average degree of the network will be almost $2m$.

We construct the existing network N_A with size $N = 1000$ and $m = 5$. The network N_B that is augmented in the existing network is considered with different size and average degree. $I = 10$ inter-network connections are created. We compare the performance of the proposed method with heuristic approaches including connecting the nodes with the highest degree or betweenness centrality from each side. Figures 1 and 2 shows the results, where outperformance of the proposed method is clear. Note that as the eigenratio R get lower values, the pinning controllability is better.

5. Conclusions

Control and synchronisation of complex networks has many potential applications in science and engineering. In this paper we considered the problem of network augmentation subject to maximising pinning controllability of the final network. A new sub-network with a specific structure is connected to an existing network with fixed topology and driver nodes. The problem is to find nodes from these two networks to create a number of inter-network connections. We used the eigenratio of the augmented Laplacian matrix, the largest eigenvalue divided by the smallest one, as a metric measuring pinning controllability of networks. Networks with lower eigenratio have better pinning controllability. We proposed a method based on graph perturbation theory and introduced a metric to find the best inter-network links. Our numerical simulations on synthetic networks showed that our proposed method outperforms heuristic methods including connecting the nodes with the highest degree or betweenness centrality from each side.

Acknowledgments

This research is supported by Australian Research Council through project No DP170102303.

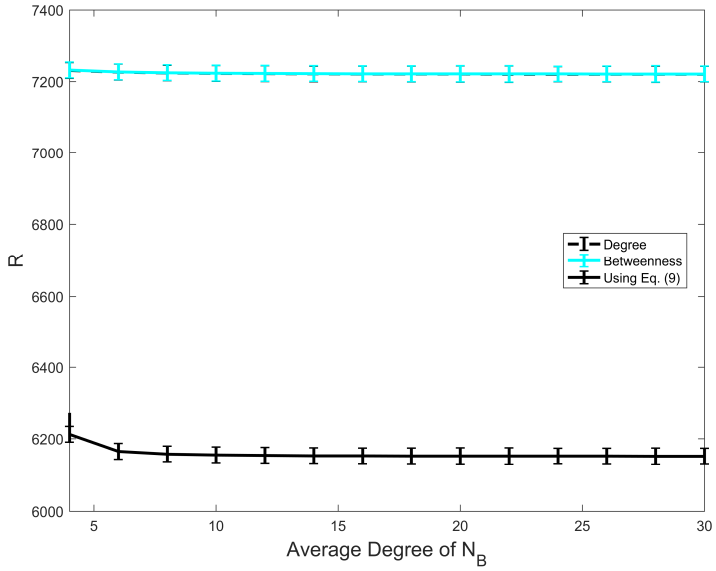

Figure1: The eigenratio R as a function of average degree (m/2) of network N_B. The size of network N_B is set to 200. I = 10 inter-networks are created based on the proposed method (black line), by connecting high degree nodes from each side (dashed black line), or by connecting those with high betweenness centrality (cyan line). Data show mean values with errorbars corresponding to the standard deviation over 50 realizations.

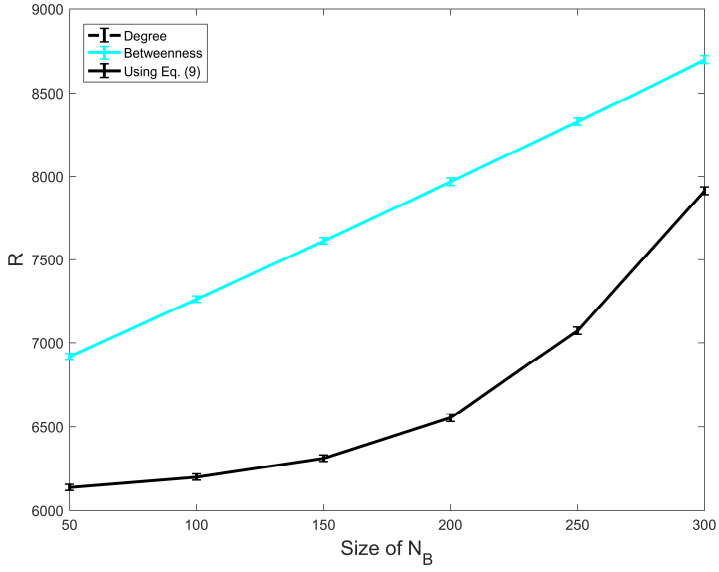

Figure 2: The eigenratio R as a function of size of network N_B. We fix m = 5. Other designations are as Figure 1.

Abstract

The aim of optimization methods consists in searching for an optimal value for a specific function within a constrained or unconstrained domain. These methods are useful for a wide range of scientific and engineering applications. Recently, a new optimization method called Jaya has generated a growing interest due to its simplicity and efficiency. In this paper, a parallel version of Jaya is developed and implemented for manycore platforms. The performance of the parallel implementation is compared with that of the sequential version of the algorithm when optimizing a function benchmark. The results indicate that the parallel Jaya algorithm achieves a significant speed-up for each of the functions, up to 190x.

Key words: Jaya, optimization, parallelism, GPU, CUDA

1. Introduction

Optimization methods are devoted to find an optimal value for a given function, generally a minimum. Each function to be optimized has its specific domain, behaviour and number of variables involved. Indeed, some of these functions have local minima, so the find of the absolute optimum can become very difficult.

Optimization methods can be mainly divided into deterministic and heuristic approaches. Deterministic approaches take advantage of the analytical properties of the function (see [1]). When coping with non-convex or large-scale optimization problems, determining the global optimum may become a very

complex task. In this case, heuristic methods should be used since they are usually more flexible and efficient than deterministic ones, and the computational time required to find the optimum can be highly reduced.

Heuristic optimization methods are classified into Evolutionary Algorithms (EA) and Swarm Intelligence (SI) algorithms. Among the EA methods, it is worthwhile mentioning Genetic Algorithm (GA), Differential Evolution (DE), Evolutionary Strategy, and some others. Among the SI methods (see [2]), it is worthwhile mentioning Particle Swarm Optimization (PSO), Artificial Bee Colony (ABC), and some others. Other methods based on nature phenomena have been developed, such as Harmony Search (HS), Biogeography-Based Optimization (BBO), and some others (see [3, 4]). The success of most of the mentioned algorithms is greatly conditioned by their specific parameters. The proper tuning of these parameters is a crucial factor for an efficient find of the global optimum.

Recently, two optimization methods have been proposed, namely TLBO (Teacher-Learner Based Optimization) [5] and Jaya [6]. Both optimizations algorithms have the advantage of not needing specific parameter tuning. They only require general parameters such as the number of iterations and the population dimension. Although they are very similar, TLBO uses two phases each one of iterations, whereas Jaya only performs one phase each one of the iterations. The Jaya algorithm has generated a growing interest in many scientific and engineering areas due to its simplicity and efficiency, see for example [7-15].

Optimization algorithms have been usually implemented on computer systems following a traditional, sequential approach. However, most of these algorithms are feasible to be decomposed into independent tasks and executed in parallel. In the last years, the performance of parallel hardware architectures has greatly increased, while their cost has been highly reduced. Nevertheless, parallelizing an algorithm is not a simple task since it requires a reformulation and adequacy to the specific architecture to be used. Among these architectures, it is worthwhile mentioning the multiprocessors and the manycore Graphics Processing Units (GPU). GPUs are originally dedicated to graphics processing but, since they have become massively parallel resources, they are suitable to be applied to other high performance processing tasks. Some research works can be found in the literature which demonstrate the advantages of executing parallel implementations of optimization algorithms on multiprocessors (see for example [16-20]) and on manycore GPUs (see for example [21-26]).

2. The Jaya Algorithm

As mentioned earlier the Jaya algorithm has the advantage of not requiring specific tuning parameter: only population size (number of different individuals) and generations (number of iterations) should be configured. This algorithm is based on the fact that the optimal solution for a given problem can be obtained moving towards the best partial solution and, at the same time, avoiding the worst

solution. Compared with other optimization methods such as GA, ABC, DDE, PSO, and TLBO, Jaya obtained better results in terms of best, mean, and worst values of different unconstrained benchmark functions [27].

The description of the Jaya algorithm is as follows. Let $f(x)$ be the objective function to be minimized (or maximized). At any iteration i, assume that there are n design variables (i.e. $j = 1, 2, \ldots, n$) and p candidate solutions (i.e. population size, $k = 1, 2, \ldots, p$). The *best* candidate obtains the best value of $f(x)$ (i.e. $f(x)_{best}$) in the whole candidate solutions, and the *worst* candidate obtains the worst value of $f(x)$ (i.e. $f(x)_{worst}$) in the whole candidate solutions. If $X_{j,k,i}$ is the value of the jth variable for the kth candidate during the ith iteration, then this value is modified by means of the following equation:

$$X'_{j,k,i} = X_{j,k,i} + r_{1,j,i} \left(X_{j,best,i} - \left| X_{j,k,i} \right|\right) - r_{2,j,i} \left(X_{j,worst,i} - \left| X_{j,k,i} \right|\right) \quad (1)$$

where $X_{j,best,i}$ is the value of the variable j for the *best* candidate, and $X_{j,worst,i}$ is the value of the variable j for the *worst* candidate.

In Equation (1) $X'_{j,k,i}$ is the updated value of $X_{j,k,i}$, and $r_{1,j,i}$ and $r_{2,j,i}$ are two random numbers in the range [0, 1], for the jth variable computed in the ith iteration. The term $r_{1,j,i} \left(X_{j,best,i} - \left| X_{j,k,i} \right|\right)$ indicates the tendency of the algorithm to move closer to the best solution, whereas the term $- r_{2,j,i} \left(X_{j,worst,i} - \left| X_{j,k,i} \right|\right)$ indicates the tendency of the algorithm to avoid the worst solution. Obviously, the new candidate ($X'_{j,k,i}$) is accepted only if it gives a better function evaluation. All the accepted function values at the end of each one of the iterations are maintained, so these values become the input to the next iteration.

3. Parallelization of Jaya

The Jaya algorithm has inherent parallel features which can be exploited. On the one hand, each candidate solution (individual $k = 1, 2, \ldots, p$ in the algorithm) into the population can independently perform the function evaluation. Moreover, each design variable ($j = 1, 2, \ldots, n$ in the algorithm) can update its value, taking into account the current best and worst values.

On the other hand, the Jaya algorithm performs some independent executions (*Runs*) of the algorithm, in our proposal we try to execute all these executions simultaneously. Considering all the computed solutions, the statistical data about the results (best, worst and mean solution, and also standard deviation) are the algorithm output.

Our parallel Jaya algorithm was designed using CUDA 7.5. Two different Nvidia Maxwell GPUs were used to evaluate the parallel performance respect to the sequential implementation, evaluated on two general purpose Intel processors. The GPUs used were the Nvidia GTX950 (768 CUDA cores, 1.025 GHz, 2 GB memory) and the GTX970 (1,664 CUDA cores, 1.05 GHz, 4 GB memory). Intel processors used were the i7-4790 (4 cores, 3.6 GHz) and the i7-6700 (4 cores, 3.4 GHz).

Both GPUs used are Maxwell Nvidia GPUs, which therefore are composed by Maxwell Streaming Multiprocessors (SMM), each one with 128 CUDA cores. Regarding the Jaya algorithm, at each iteration the updated whole population have to be shared for all threads involved in the computing, thus, in order to obtain good parallel behaviour, the population data should be stored in the shared memory. Given that the shared memory is owned by each SMM, each independent execution of the algorithm is mapped on one SMM, thus the number of thread blocks in the grid of the kernel launched is equal to the desired number of independent executions (*Runs*). On the other hand, the number of threads per block in the grid were configured in a 2D array, being the row size equal to the population size and the column size is equal to the number of design variables, which depends on the function to be optimized. The shared memory is used to store: the whole population, the partial values of the function evaluation, the new candidates, and other data as for example the indices of the current best and worst solution. Each thread performs the updating of one design variable and computes the part of the function evaluation corresponding to the assigned design variable. Only one thread have to perform the reduction process of computing the final value of the global function evaluation for each specific individual. Note that the partial values of the function evaluation have to be stored in the shared memory, increasing the shared memory requirements, to be able to efficiently carry out the last reduction process. Figure 1 depicts the parallel computing of the partial values of the function evaluation for whole population respect to each thread block, where P is the population size and N is the number of the design variables of the function to be optimized. N that the value of P is assigned as tuning parameter while the value of N cannot be modified since it is inherent to the chosen function.

Worthy to note that the shared memory performance and the available amount is a key to obtain good speed-ups. On the one hand the shared memory performance allows share efficiently the data involved in the computing, and on the other hand the amount of shared allows to increase the population size.

4. Experimentation

The comparison between the sequential and the parallel implementations of the algorithm was made taking into account 30 unconstrained functions frequently used as a well-known benchmark in several works about optimization. First, the Rosenbrock function was chosen so as to provide a complete set of statistical results. This function is usually defined with 30 design variables.

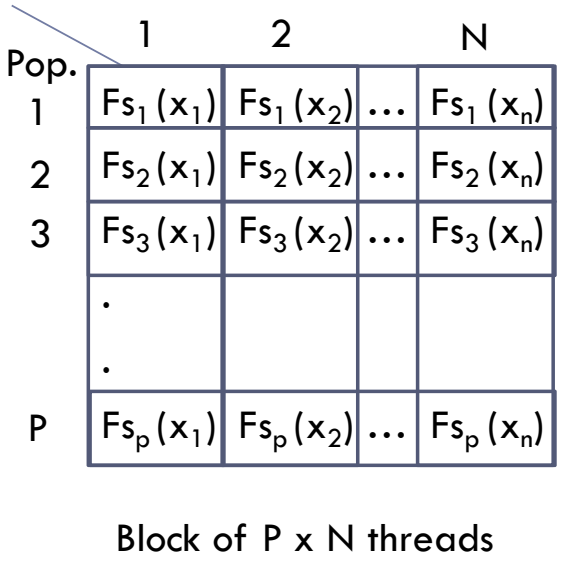

Figure 1. Data computing distribution for one independent run (block).

The number of iterations was fixed to 30,000. Two parameters were modified so as to evaluate the speed-up when compared with the sequential implementation and the error in the function optimization: number of *Runs* (which value sets the number of thread blocks) was varied in the set of values {2, 4, 8, 16, 32, 64, 128, 256}; with regard to population size (number of individuals), its value was varied within the set {8, 16, 32}. Figure 2 shows the speed-up achieved when comparing the parallel implementation on the Nvidia GTX970 GPU with the sequential execution on the Intel i7-4790 processor. The X-axis corresponds to the number of independent executions (*Runs*), whereas each bar from left to right within a specific value of *Runs* corresponds to a population size of 8, 16, and 32 individuals respectively. Obviously, when the value of *Runs* is lower than the number of MSS (13 for the Nvidia GTX970) the GPU cannot be fully occupied obtaining low speed-up values. It can be observed that a maximum speed-up higher than 50x was obtained with 64 *Runs* and a population size of 8. In this case, the error was in the order of 10^{-3} for both the sequential and the parallel implementations. Worthy to note that the parallel performance improves as the population size decreases, this is due to the reduction processes become more significant respect to the total computational cost. Obviously the optimal population size depends on the computational cost of the function evaluation to be optimized.

Second, the full set of unconstrained functions was also optimized by means of the sequential and the parallel version of the Jaya algorithm. Speed-up was calculated by following the same criteria as with the Rosenbrock function with regard of fixed number of iterations, number of independent executions, and population size. Remark that, depending on the function to be optimized, the

value of *Runs* were increased up to 1024, whereas in other cases this parameter had to be decreased to 128 or even 64 due to the features of the GTX950 GPU. Figure 3 shows the maximum speed-up obtained when optimizing the whole benchmark functions. It can be observed that, in some cases, the speed-up is higher than 100x. Indeed, in case of F05 (the Matyas function), the speed-up is near 190x with a population size of 64 and 1024 *Runs*. Table 1 shows the value of *Runs* and the population size related to the maximum speed-up obtained for each one of the benchmark functions.

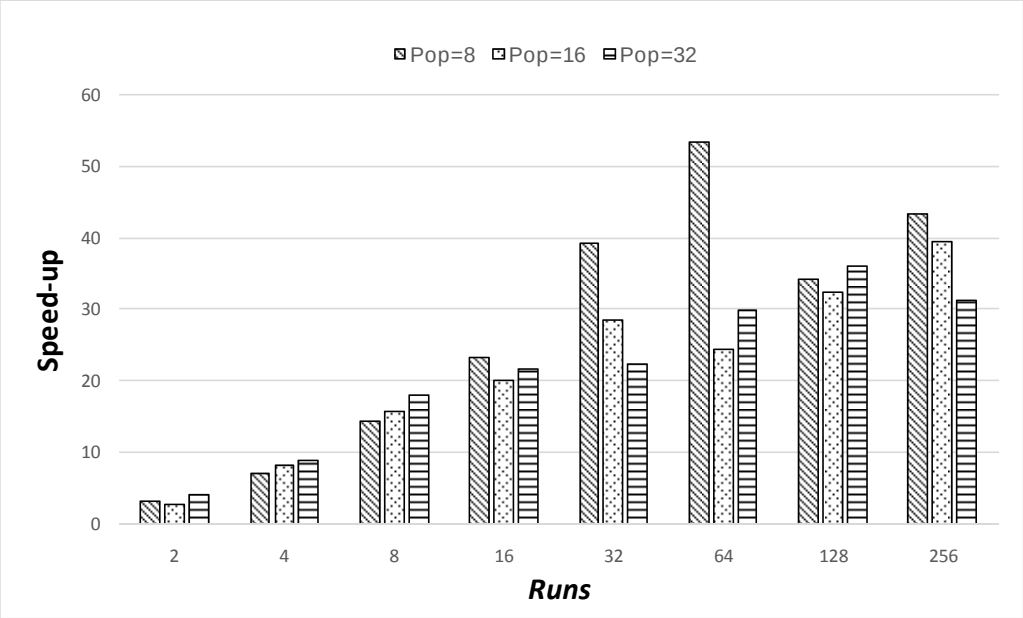

Figure 2. Speed-up obtained for the Rosenbrock function with different independent executions (*Runs*) and population sizes.

5. Conclusions

In this work, a parallelization of Jaya, a recent optimization algorithm, is proposed. The algorithm is implemented in a manycore GPU platform using CUDA, and its performance is compared with that of a conventional sequential version of the algorithm implemented in general purpose processors. Results obtained using two different GPUs are tested by means of a benchmark of 30 unconstrained functions. The results of the experimentation demonstrate that the parallel implementation of Jaya on GPUs provides a significant speed-up when compared with the sequential execution. In the best case, the speed-up rises to 190x, being the mean speed-up for the 30 benchmark functions equal to 53x, whereas the median is 41x.

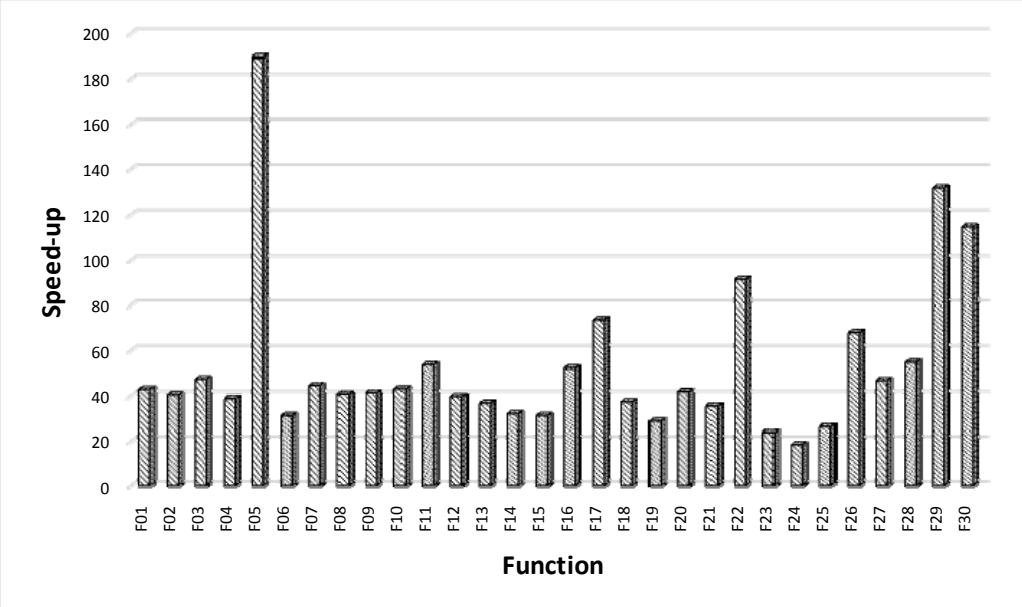

Figure 3. Maximum speed-up for the 30 benchmark functions.

Table 1. Population size and *Runs* at the maximum speed-up for the 30 benchmark functions.

As future work, new benchmark functions should be analysed so as to obtain additional performance results of the parallel Jaya algorithm, paying special attention to constrained functions. Furthermore, other optimization algorithms should be parallelized and implemented on manycore platforms and compared to the Jaya algorithm.

Helical Gold Nanorod and Chiral Gold Nanocage Structures

Xiaojing Liu [1] and Ian Hamilton[2]

[1] *Department of Chemistry, Wilfrid Laurier University, Waterloo, ON, Canada N2L 3C5*

emails: xxliu@wlu.ca, ihamilton@wlu.ca

Abstract

We present intrinsically chiral gold Au_{9n+6} structures consist of an Au_{9n} tube which is capped with Au_3 units at each end. The intrinsic chirality of these structures results from the helicity of the gold strands which form the tube and not because an individual Au atom is a chiral center. The symmetry of these structures is C_3 and substructures of gold hexagons with a gold atom in the middle are particularly prominent.

Key words: gold nanostructures, relativistic density functional theory

Introduction

Gold nanoparticles have received a great deal of attention due to their size-related properties which can differ significantly from those of bulk gold. Thus, whereas bulk gold is inert, it was shown that gold nanoparticles are effective catalysts for the oxidation of carbon monoxide and a number of other chemical reactions.

For gold clusters, compact, tube, and cage structures have all been shown to be stable. Cage structures are of particular interest because it may be possible to encapsulate (and stabilize) species inside the cage.

There are a number of instances in which chirality is induced in a gold cluster by chiral ligands or a chiral arrangement of achiral ligands and this chirality may be retained if the ligands are subsequently removed. However, there are only a few instances in which a bare gold cluster is intrinsically chiral.

Results

We have established the stability of helical gold nanorods with 24, 32, and 40 gold atoms.[1] These structures have a core comprised of a linear strand of 3, 4, and 5 gold atoms and a shell comprised of seven helical strands of 3, 4, and 5 gold atoms. We have studied the IR spectra of these species and also the corresponding vibrational circular dichroism (VCD) spectra. A detailed examination of the VCD spectra with adsorbed CClHDT allowed us to establish helical gold nanorods as chiral recognition nanostructures.[2] Starting from the helical gold nanorods, removing the central linear strand, increasing the number of helical strands, and capping the resulting helical gold nanotube at each end, we obtain a series of chiral gold nanocage structures. These gold nanorod and nanocage structures, which exhibit unique electronic and magnetic properties, have potential use in chiral catalysis and as components in nanostructured devices.

Hopf and homoclinic bifurcation of a new SEIRS epidemic model

M.P. Markakis[1] and P.S. Douris[1]

[1] *Department of Electrical & Computer Engineering, University of Patras, GR 26504, Greece*

e-mails: markakis@upatras.gr, pandouris@ece.upatras.gr

Abstract

A new SEIRS epidemic model with nonlinear incidence rate and nonpermanent immunity is presented in the present paper. Initially, a stability analysis is performed and we proceed to the determination of the necessary and sufficient conditions for the occurence of Hopf bifurcation of codimension 1 or higher. The fact that the incidence rate per infective individual is given by a nonlinear function, product of rational powers of two state variables leads to a more realistic modeling of the physical problem itself. A stability analysis is performed and the features of Hopf bifurcation are investigated. Both the corresponding critical regions in the parameter space and their stability characteristics are presented. Furthermore, by using algorithms based on a new symbolic form as regards the restriction of an n-dimensional nonlinear parametric system to the center manifold and the normal forms of the corresponding Hopf bifurcation, as well, the associated bifurcation diagram is derived. Also, various emerged limit cycles, as well as a homoclinic point-to-point (P2P) connecting orbit are numerically obtained by appropriate implemented methods.

Keywords: Epidemic models; Hopf bifurcations; Limit cycle, Homoclinic P2P connection

1. Introduction

In this paper we present a new epidemic SEIRS model with nonlinear incidence rate and nonpermanent immunity. We deal with the stability analysis and we proceed to the determination of the necessary and sufficient conditions for the occurrence of Hopf bifurcation of codimension 1 and 2. The problem is governed by the following 4D differential dynamical system:

$$\begin{aligned}
&\dot{S} = rN - dS + \varepsilon R - h(S,I)I \\
&\dot{E} = -(d+\sigma)E + h(S,I)I \\
&\dot{I} = -(\gamma + d + a)I + \sigma E \\
&\dot{R} = \gamma I - (d+\varepsilon)R \\
&and \\
&\dot{N} = rN - dN - aI
\end{aligned} \tag{1.1}$$

where S, E, I, R, N denote the number of susceptible, exposed (incubating), infective, recovered individuals and the total population, respectively, while $r, d, \varepsilon, \sigma, \alpha, \gamma$ stand for the system parameters and $h(S,I)$ is the incidence rate per infective individual. Regarding their physical meaning, r denotes the birth rate, d denotes the physical death rate, ε denotes the rate of loss of immunity, σ denotes the rate of incubation, α is the additional death rate due to the epidemic, and γ is the recovery rate. By setting

$$h(S,I) = \beta S^m I^{s-1} / N^{m+s-1} \tag{1.2}$$

with β, m, s positive constants ($s > 1$), and normalizing with respect to the total population N, which is considered constant, taking into account the latter of (1.1), the above system is reduced to a 3D one, namely

$$\begin{aligned}
&\dot{x} = r + \varepsilon - (r+\varepsilon)x - \varepsilon w - \varepsilon y + axy - \beta x^m y^s \\
&\dot{w} = -(r+\sigma)w + awy + \beta x^m y^s \\
&\dot{y} = \sigma w - (r + \gamma + \alpha)y + ay^2
\end{aligned} \tag{1.3}$$

where $x = S/N,\ w = E/N,\ y = I/N$ and $x + w + y + z = 1$. The analysis is multi-parametric, meaning that the parameter space of the system is structured by three varying parameters. In Section 2 a stability analysis of the system is performed, where the active parameters are determined and various graphical representations are obtained concerning the critical (with respect to Hopf bifurcations) values of the varying parameters, as well as the critical, noncritical and stability regions in the parameter space considered. Via effective algorithms based on a new proper symbolic form regarding the center manifold (see [4]), and carried out using the symbolic computation software Mathematica, the corresponding bifurcation portraits are plotted throughout the regions of the parameter space under consideration. Using a custom multiple shooting method, as well as a modified orthogonal collocation method on finite elements, limit cycles corresponding to the cases resulted from the analysis and a homoclinic P2P connecting orbit are presented together with the associated technical details.

2. Stability analysis – Hopf bifurcation

The final reduced system (1.3) possesses two types of equilibria; a disease-free one, namely

$$\Sigma_0 = (1,0,0) \tag{1.4}$$

and an endemic one of the form $\Sigma_1(x^0, y^0, z^0)$ with $y^0 \neq 0$ obtained after some tedious algebraic manipulations, as

$$x^0 = \frac{1}{\sigma\left(\alpha y^0 - \kappa_0\right)}\left[\alpha^2\left(y^0\right)^3 - \alpha\kappa_4\left(y^0\right)^2 + \left(\kappa_3 + \sigma\varepsilon\right)y^0 - \sigma\kappa_0\right] \tag{1.5}$$

$$\beta\sigma\left(x^0\right)^m\left(y^0\right)^{s-1} = \alpha^2\left(y^0\right)^2 - \alpha\left(\kappa_4 - \varepsilon\right)y^0 + \kappa_3 - \varepsilon\kappa_2 \tag{1.6}$$

$$w^0 = \frac{1}{\sigma}\left[-\alpha\left(y^0\right)^2 + \kappa_2 y^0\right] \tag{1.7}$$

where $\kappa_0 = r + \varepsilon,\ \kappa_1 = r + \varepsilon + \sigma,\ \kappa_2 = r + \gamma + \alpha,\ \kappa_3 = \kappa_1\kappa_2,\ \kappa_4 = \kappa_1 + \kappa_2$. We focus on the endemic equilibrium $\Sigma_1 = \left(x^0, y^0, w^0\right)$ with x^0, y^0, w^0 given in (1.5) - (1.7), since it corresponds to persistence of the disease.

Regarding the local stability of Σ_1, taking into account Eqns. (1.5), (1.6) and (1.7), the Jacobian matrix evaluated at Σ_1 becomes

$$J_0 = \begin{pmatrix} \alpha y^0 - \kappa_0 - \dfrac{m}{\sigma}A\dfrac{y^0}{x^0} & -\varepsilon & -\varepsilon + \alpha x^0 - \dfrac{s}{\sigma}A \\ \dfrac{m}{\sigma}A\dfrac{y^0}{x^0} & \alpha y^0 - \kappa_1 + \varepsilon & \dfrac{\alpha}{\sigma}\left[-\alpha\left(y^0\right)^2 + \kappa_2 y^0\right] + \dfrac{s}{\sigma}A \\ 0 & \sigma & 2\alpha y^0 - \kappa_2 \end{pmatrix} \tag{1.8}$$

where

$$\begin{aligned} &y^0 = y^0\left(\gamma, r, \alpha, \varepsilon, \sigma, \beta, m, s\right), \quad x^0 = x^0\left(y^0; \gamma, r, \alpha, \varepsilon, \sigma\right), \\ &A = A\left(y^0; \gamma, r, \alpha, \varepsilon, \sigma\right) = \alpha^2\left(y^0\right)^2 - \alpha\left(\kappa_4 - \varepsilon\right)y^0 + \kappa_3 - \varepsilon\kappa_2 \end{aligned} \tag{1.9}$$

The associated characteristic equation is

$$\lambda^3 + B_2\lambda^2 + B_1\lambda + B_0 = 0 \tag{1.10}$$

By considering the well-known Routh-Hurwitz necessary and sufficient stability conditions, namely

$$B_0 > 0, \quad B_1 > 0, \quad B_1B_2 - B_0 > 0, \tag{1.11}$$

related to the equilibrium Σ_1, we conclude with the formulas

$$\begin{aligned} &B_0 = \frac{1}{\sigma x^0}\left(P_{00} + P_{01}x^0\right), \quad B_1 = \frac{1}{\sigma x^0}\left(P_{10} + P_{11}x^0\right), \\ &B_3 = B_1B_2 - B_0 = \frac{1}{\sigma^2\left(x^0\right)^2}\left(P_{30} + P_{31}x^0 + P_{32}\left(x^0\right)^2\right), \end{aligned} \tag{1.12}$$

where $P_{ij} = f_{ij}(y^0; \gamma, r, \alpha, \varepsilon, \sigma, m, s),\ i = 0,1,3,\ j = 0,1,2$ are polynomials with respect to y^0. By solving the equation $B_3 = 0$ (resulting from (1.10) for $\lambda = i\omega$) with respect to y^0 (after substitution of the right-hand side of (1.5) for x^0, we evaluate the real

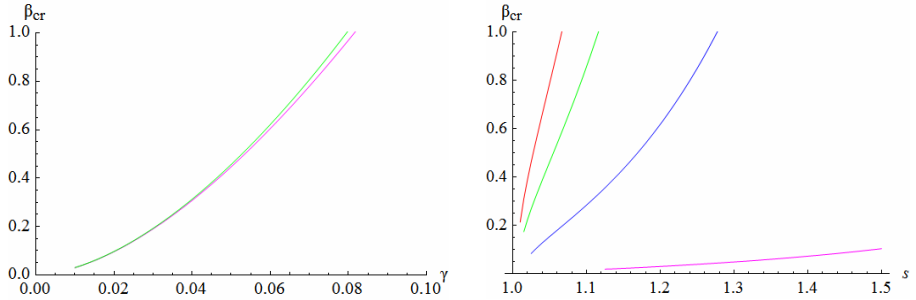
roots of a 9th degree polynomial numerically), we further evaluate x^0 and w^0 by substituting the obtained root of B_3 into (1.5) and (1.7), respectively. Then, taking into account that $\kappa_2 > \alpha$, we arrive at $w^0 > 0$ by means of (1.7) in the case where $0 < y^0 < 1$. Thus if

$$0 < x^0 < 1, \quad 0 < y^0 < 1, \quad w^0 < 1, \quad B_0 > 0, \quad B_1 > 0 \tag{1.13}$$

then (x^0, y^0, w^0) represent the critical values $(x^0_{cr}, y^0_{cr}, w^0_{cr})$. Then, by solving (1.6) with respect to β and considering (γ, σ, β) varying parameters of the problem we obtain the critical value

$$\beta_{cr} = \frac{\alpha^2 \left(y^0_{cr}\right)^2 - \alpha\left(\kappa_4 - \varepsilon\right) y^0_{cr} + \kappa_3 - \varepsilon\kappa_2}{\sigma \left(x^0_{cr}\right)^m \left(y^0_{cr}\right)^{s-1}} \tag{1.14}$$

provided that $0 < \beta_{cr} < 1$, where x^0_{cr}, y^0_{cr} the aforementioned critical equilibrium of the system (1.1). Thus a *critical surface* $\beta_{cr} = \beta_{cr}(\gamma, \sigma)$ is generated in the parameter space (γ, σ, β), (we have $y^0_{cr} = y^0_{cr}(\gamma, \sigma)$ and due to (1.5) we also have $x^0_{cr} = x^0_{cr}(\gamma, \sigma, y^0_{cr}(\gamma, \sigma))$, with $r, \alpha, \varepsilon, m, s$ fixed), defined over the area of the parameter plane (γ, σ), where the critical values of β are obtained via (1.13) and (1.14); we call this area *critical region*. Moreover, by evaluating the appropriate derivatives with respect to the active parameters (γ, σ, β), according to Liu criterion [5], the *transversality condition* holds. Hence, a Hopf bifurcation occurs at the critical equilibrium. Graphical representations of β_{cr} (evaluated by using (1.14)) versus γ (for different values of σ, with $r, \alpha, \varepsilon, m, s$ fixed) and versus s (for different values of γ, with $r, \alpha, \varepsilon, \sigma, m$ fixed) are presented in Figures 1a, 1b and 1c, respectively, while *critical regions* are obtained in the parameter plane (γ, σ) for fixed values of $r, \alpha, \varepsilon, m, s$ in Figures 2a and 2b.

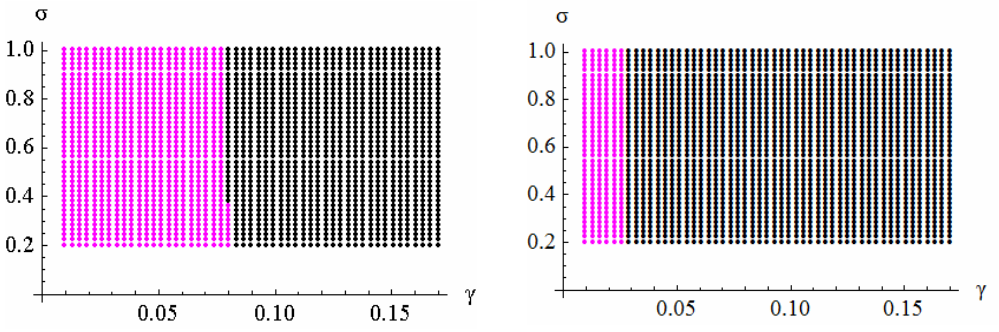


(a) **(b)**

Fig.1 The critical value, β_{cr}, as a function of the parameters: **(a)** γ for $\sigma = 0.25$ (magenta), $\sigma = 0.75$ (green), **(b)** s for $\sigma = 0.5$ and $\gamma = 0.01$ (magenta), $\gamma = 0.06$ (blue), $\gamma = 0.12$ (green), $\gamma = 0.17$ (red).

We note that variation of the values of fixed parameters does not affect the

number of critical values as regards β. Thus in any case, the expression (1.13), under restrictions (1.14), yields zero or at most one critical value ($0<\beta_{cr}<1$). Additionally, we note that an increase in s or m gives rise to an expansion of the *zero region*, namely the area of the parameter plane (γ,σ) where no critical values of β exist. Furthermore, the status of the equilibrium points corresponding to the values of β in the range $(0,1)$, is shown in Figures 3a and 3b. More precisely, after the right-hand side of (1.5) has been substituted for x^0, by using standard numerical computation routines, Eqn. (1.6) is solved with respect to y^0 for any given value of β and fixed values for the other parameters.

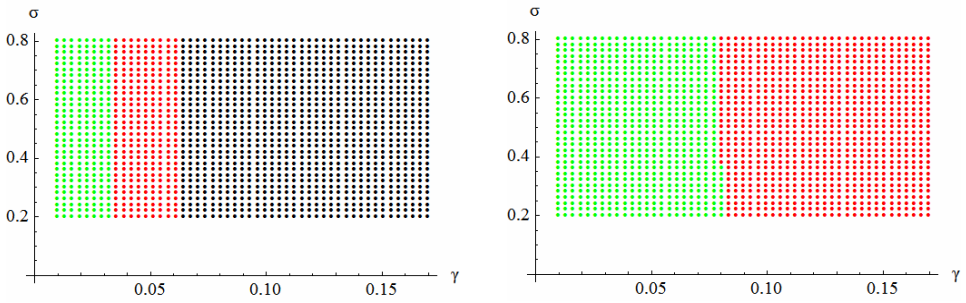


(a) **(b)**

Fig.2 *Critical regions* (magenta – one critical value for β) and *zero regions* (black – no critical value for β), for $r=10^{-4}$, $\alpha=10^{-4}$, $\varepsilon=10^{-3}$, $m=0.5$ and **(a)** $s=1.2$, **(b)** $s=1.6$.

Then x^0 and w^0 can be obtained by means of (1.5) and (1.7), respectively, and finally the coefficients B_i, $i=0,1,2$ of the characteristic equation (1.10) are determined. Thus, concerning the *critical* pairs (γ,σ) (the points of the *critical region*), we focus on the slope of the real part of the complex conjugate eigenvalues of the Jacobian as a function of β, inside an interval $(\beta_{cr}-d_1,\beta_{cr}+d_2)$, $d_1,d_2>0$ (where a pair of complex eigenvalues exist), in order to determine the direction and stability of the occurring codimension 1 Hopf bifurcation. As regards the *zero regions* (no β_{cr}), one investigates the existence of equilibrium points, as well as their stability, as β varies within the range $(0,1)$. As a result, we conclude that regardless of the parameter values, the real part of the complex eigenvalues transverses the β- axis (at β_{cr}) with negative slope, all over the *critical surface* (for β lying into the aforementioned "complex" interval, the sign of the real eigenvalue is always negative). Moreover, we encounter an unstable endemic equilibrium depending on β in the *zero regions*, for this active parameter lying inside an interval $(\delta,1)$, $\delta=\delta(\gamma,r,\alpha,\varepsilon,\sigma,m,s)>0$ (we have no equilibria at $(0,\delta)$), with δ notably sensitive to γ- variation, in the sense that as

γ increases, δ shifts rapidly towards unity, shrinking the (unstable) "equilibrium" β - interval. By increasing s or m, a "0 - equilibrium" region is emerged inside the *zero region* (there exist no equilibria in the whole range $(0,1)$), getting larger as these two rational exponents (especially s) increase.



(a) **(b)**

Fig.3 Stability features regarding the *critical* (green) and the *zero* (black and red) *regions*. Green denotes the negative slope of the real part of the complex eigenvalues versus β, around β_{cr}, red indicates the existence of unstable endemic equilibria for $\beta \in (\delta,1)$ and black outlines the pairs (γ,σ) for which no endemic equilibria arise in the whole range $(0,1)$ for β. The parameters are defined as: $r=10^{-4}$, $\alpha=10^{-4}$, $\varepsilon=10^{-3}$, $m=0.5$ and **(a)** $s=1.2$, **(b)** $s=1.6$.

3. Continuation of limit cycles via multiple shooting - Point-to-point homoclinic orbit

The stable limit cycles emerging from the supercritical Hopf bifurcation of the endemic equilibrium Σ_1 are numerically continued with respect to the fundamental period with one active parameter, the transmission coefficient β, via a custom multiple shooting algorithm with an integral phase condition. For the numerical continuation of the limit cycles of interest the original system is transformed to:

$$\dot{u} = T_p f(u,\alpha) \tag{3.1}$$

by use of the time scaling $\tau = t/T_p$, which maps the independent variable $[0,T_p]$ to $[0,1]$, so that the period appears explicitly as a system parameter. Then, the time variable lies in $[0,1]$ and this interval is subdivided into a total number of $N+1$ mesh points and consider a number of initial conditions, s_i, $i=1,2,..,N$ along an initial approximation of the limit cycle of interest. The problem to be solved numerically is:

$$\dot{u} = T_p f(u,a),\ u(t_i) = s_i,\ u,s \in \mathbb{R}^n,\ \alpha \in \mathbb{R} \tag{3.2}$$

where $t_i \le t \le t_{i+1}$ for $i=1,2,..,N$ within $[0,1]$. Last, a phase condition is needed in order to fix the time-shift. An integral phase condition has been used:

$$\int_0^1 \dot{\hat{u}}(t)\left[u(t)-\hat{u}(t)\right]dt=0 \tag{3.3}$$

where $\hat{u}(\tau)$ represents an initial guess for the solution, typically obtained from the previous continuation step. As soon as the active parameter remains practically unchanged and the step of continuation greatly increases, a good enough initial approximation of the homoclinic orbit has become available. Now, consider the parameterized differential system of interest. Assuming that this system possesses one hyperbolic equilibrium, $z_{\pm}$. we call a solution $z(t)$, for $-\infty<t<+\infty$, of the system at $a=a_0$ a homoclinic connecting orbit (to this equilibrium) if the limit:

$$z_{\pm}=\lim_{t\to\pm\infty} z(t) \tag{3.4}$$

exists. As long as f is continuous $z_{\pm}$ is a stationary point, so:

$$f(z_{\pm},a_0)=0 \tag{3.5}$$

Regarding the numerical computation of a homoclinic orbit, the infinite time horizon $(-\infty,+\infty)$ is truncated to a finite one of the form $[T_-,T_+]$, so that the system is transformed to:

$$\dot{u}=2Tf(u,\alpha) \tag{3.6}$$

accompanied by the integral phase condition (3.3).

In order to determine the number of parameters, p, for which the connecting orbits are isolated and structurally stable phenomena in the system and the orbits of the system appear in a generic manner, we assume that (2.16) possesses the stationary point of interest, $z_{\pm}$. These stationary points are in fact two invariant sets of the system, $M_-,M_+\subset\mathbb{R}^{n+p}$, respectively and the orbit $\gamma=\{(z(t),\mu(t)):\ t\in\mathbb{R}\}$ where $q=(z,\mu)\in\mathbb{R}^{n+p}$ is the connecting orbit pair with:

$$\dot{z}=g(z)=(f(z,\mu),0) \tag{3.7}$$

is called a connecting orbit from M_- to M_+ if:

$$dist(z(t),M_{\pm})\to 0 \text{ as } t\to\pm\infty \tag{3.8}$$

If $M_{\pm}(\mu)$ have stable manifolds $M_{\pm s}(x_-)$ and unstable manifolds $M_{\pm u}(x_+)$ and the dimensions of these manifolds are $n_{\pm c}+n_{\pm s}$, $n_{\pm c}+n_{\pm u}$, respectively, so that $n=n_{\pm c}+n_{\pm s}+n_{\pm u}$. For the steady case, however, $n_{-c}=n_{+c}=0$, so $n_{\pm u}=n-n_{\pm s}$, since $M_-(\mu)$ is a hyperbolic equilibrium $x_-(\mu)$ of (3.7) and $M_+(\mu)$ is also a hyperbolic equilibrium $x_+(\mu)$ of (3.7). We expect the orbit γ to be an isolated connecting orbit if [8]:

$$T_{z(t)}M_{-u}\cap T_{z(t)}M_{+s}=T_{z(t)}\gamma=span\{\dot{z}(t)\} \text{ for all } t\in\mathbb{R} \tag{3.9}$$

for the tangent spaces at $z(t)$. Furthermore, the connecting orbit is persistent in $p-$parametric systems as long as the intersection is transversal, that is if

$$T_{z(t)}M_{-u}+T_{z(t)}M_{+s}=\mathbb{R}^{n+p} \tag{3.10}$$

holds. So, based on (3.9), (3.10) we get:

$$p = m_{+u} - m_{-u} + 1 \tag{3.11}$$

Since the orbit sought is a homoclinic point-to-point one, then $m_{+u} = m_{-u}$, so according to (3.11) $p = 1$, so β has been chosen as the active parameter. The numerically continued cycles are presented in the following Figure:

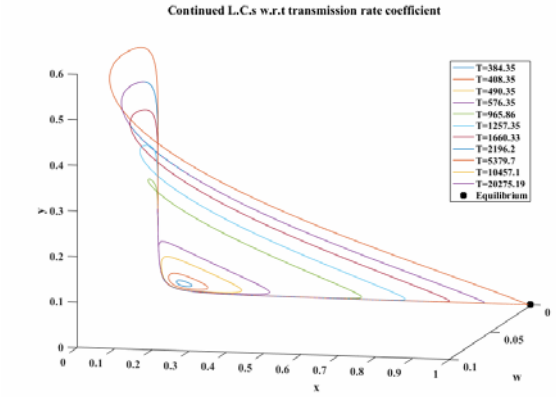


Fig. 4.1 Numerically continued limit cycles emerging from a supercritical Hopf bifurcation

4. High order accurate boundary conditions

An appropriate combination of multiple scales approximation method and that of successive approximations leads to a technique for the determination of high order accurate boundary conditions for the numerical location of homoclinic P2P orbits. Both the widely used techniques of projection boundary conditions and the method of eigenvectors are first order accurate thus requiring quite good initial data for the successful computation of the orbits of interest and this is becoming harder and harder to achieve as the number of state variables together with the number of active parameters increases. A quick description of the technique follows. Consider the dynamical differential system (3.7) and let this system possess a number of fixed points, from which $E_1(z_1^0, z_2^0, .., z_n^0)$ is the fixed point of interest (i.e. the one associated with the homoclinic P2P orbit). Then E_1 is translated to $O(0,0,..,0)$ via the transformation:

$$\xi = z - z^0,\ z \in \mathbb{R}^n \tag{3.12}$$

and z^0 the coordinates of E_1, that is $z^0 = \left(z_1^0, z_2^0, .., z_n^0\right)^T$, so that the initial differential system becomes:

$$\dot{\xi} = f\left(\xi, a\right),\ \xi \in \mathbb{R}^n,\ a \in \mathbb{R}^1 \tag{3.13}$$

and assuming the solution of interest can be approximated up to the order of interest in positive integer powers of a small amplitude orbital parameter, ε, as:

$$\xi(t) = \sum_{i=1}^{k} \varepsilon^i \varphi_i(t) \tag{3.14}$$

where k is the desired order of approximation (Deprit and Henrard, 1965) we insert $\xi(t)$ of (3.13) in the translated system due to (3.12), that is in (3.14) and we equate the terms of the same order, thus getting k first order differential systems, one for each order of approximation. Then, further assuming the fixed point of interest is hyperbolic (i.e. no eigenvalue associated with it is trivial), we set the initial conditions of the first order approximation corresponding to the eigenspace of interest equal to zero. Thus, the first order systems of the desired order of approximation (scale order) are extracted. Let us describe the definition and application of high order B.C.'s. Assuming the solutions of the dynamical differential system of interest can be approximated by:

$$x_{i,j}(t) \approx \sum_{j=1}^{j_{\max}} \varepsilon^j x_{i,j}(t) \tag{3.15}$$

where x_i, $i=1,2,3$ are the state variables (i.e. $x_1(t)=x(t)$, $x_2(t)=w(t)$, $x_3(t)=y(t)$), ε denotes the orbital parameter and $j_{\max}$ is the maximal scale order (i.e. power of ε) or equivalently the highest order of approximation. Then, by substituting the expressions of (3.15) into (1.1) and equating the terms of the same order, we get the respective linear systems of ordinary differential equations (ODEs for short). Thus, the state variables axes of (1.1) are translated by setting:

$$\Delta x_i = x_i - x_i^*,\ i=1,2,3 \tag{3.16}$$

where x_i^*, $i=1,2,3$ are the values of the equilibrium of interest, so that the new equilibrium point of the translated system now becomes $O(0,0,0)$ and the right-hand sides of (1.1) are generally expanded in a Taylor series and terms up to the fourth order are kept, so that 4th order accurate boundary conditions are extracted. Thus, the linearized systems of each order of approximation for the determination of both the outgoing and the incoming solution vector can be obtained. By successively solving the linearized systems of ordinary differential equations and choosing the appropriate initial conditions for each solution, the boundary conditions up to the desired order become available by use of (3.15). Regarding the approximation of the outgoing (incoming) solution vector, the solution of the corresponding system is obtained for every order of approximation and the integration constants corresponding to the eigenvalues [or the eigenvalues with negative (positive) real part more generally] are set equal to zero. Then, the total approximation up to the order of interest is of the form:

$$\Delta x_i(t) \approx \varepsilon \Delta x_{i,1}(t) + \varepsilon^2 \Delta x_{i,2}(t) + \varepsilon^3 \Delta x_{i,3}(t) + \varepsilon^4 \Delta x_{i,4}(t) \tag{3.17}$$

The solutions of the linearized systems of successive (order) approximations for the outgoing solution vector (i.e. associated with the unstable manifold of the equilibrium, to which the orbit under consideration is homoclinic) are presented:

k order approximation for outgoing (unstable) solution vector:

$$\Delta x_{i,k}(t) = q_{xi,k} c_1^{\,k} e^{k\lambda_u t} \tag{3.18}$$

for $i=1,2,3$, $k=1,2,3,4$, where c_1 denotes the integration constant corresponding to the locally asymptotically unstable solution mode (i.e. the positive eigenvalue

of the Jacobian matrix linearized around the equilibrium of interest) in (3.18) and q_{xi}, q_{wi}, q_{yi}, for $i = 1,2,3$ are parameters associated with the numerical values of the chosen system parameters. The systems are solved sequentially and all the rest integration constants (i.e. except for c_1) are set equal to zero. The effectiveness of the higher order approximations is presented in Figure 4.2

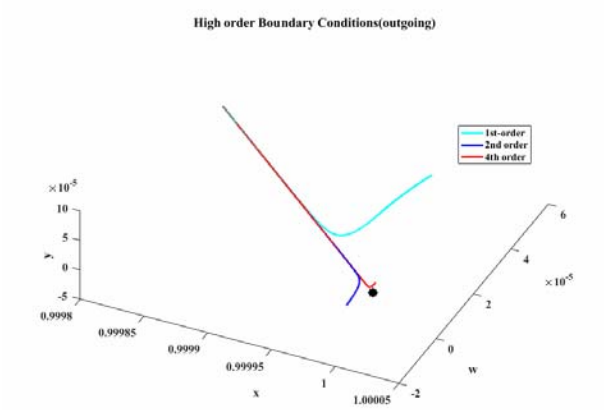

Fig. 4.2 Effectiveness of high order boundary conditions

Thus, the high order B.C.'s for the computation of the homoclinic orbit are (See (3.6)):

$$g(s_1, s_N) = c_{w,j1}\left(x_{j0} - \Delta x_{j_{out}}\right)^2 + c_{w,j2}\left[x_j(\tau = 1) - \Delta x_{j_{in}}\right]^2 \tag{3.19}$$

for $j = 1,2,3$, where $s_1 = [x(\tau = 0; s_1), w(\tau = 0; s_1), y(\tau = 0; s_1)]^T = [x_0, w_0, y_0]^T$ and $c_{w,xjm}$, m=1,2 for are some weighting (scaling) coefficients (all of which have been set equal to 1 in the present case). By employing the aforementioned high order boundary conditions a faster, more efficient computation of the homoclinic orbit of interest is possible.

The transversality of the homoclinic orbit can be verified by use of the Mel'nikov integral. If that integral is not equal to zero, then the homoclinic orbit is transversal, meaning that the stable and the unstable manifold associated with the equilibrium point of the homoclinic orbit intersect transversally. So, consider the extended system:

$$\dot{z} = f(z, a),\ z \in \mathbb{R}^n,\ a \in \mathbb{R}^1,\ \dot{\alpha} = 0 \tag{3.20}$$

and the extended vector of phase variables is $(z, \alpha)^T \in \mathbb{R}^{n+1}$. Also, let (3.20) possess a P2P homoclinic orbit for $a = a_c$ denoted H_c around the saddle equilibrium $z_0(a_c)$, where $z_0(a)$ represents a one-parameter family (curve) of saddle equilibria. This curve has an unstable manifold W^u and a stable manifold W^s. For a specific value of the system parameter a, the corresponding slices of these manifolds coincide with the unstable and stable (respectively) manifolds of

the saddle $z_0(a)$. Consider the linearization of (3.20) around the homoclinic orbit $z_h(t)$ at $\alpha = \alpha_c$:

$$\dot{\gamma} = f_z\left(z_h(t), a_c\right)\gamma + f_a\left(z_h(t), a_c\right)\mu,\ \dot{\mu} = 0 \tag{3.21}$$

Then $\dot{z}_h(t)$ (and every scalar multiple of it) is the unique solution to the variational equation around. The adjoint variational equation around H_c is:

$$\dot{\theta} = -A^T(t)\theta,\ \theta \in \mathbb{R}^n \tag{3.22}$$

where $A(t) = f_z(z_h(t), \alpha_c)$ and it has a unique bounded solution denoted by $\theta(t) = \delta(t)$. Thus, the nondegeneracy (or regularity) of the homoclinic orbit is equivalent to the transversality of the intersection of W^u and W^s along in the extended $n+1$-dimensional phase space of (3.20) and it translates to the condition

$$M_a(a_c) = \int_{-\infty}^{+\infty} \left\langle \delta(t), f_a\left(z_h(t), a_c\right)\right\rangle dt \neq 0 \tag{3.23}$$

which is the Mel'nikov integral. If a scalar function, $M(a)$, measuring the displacement of the invariant manifolds is defined, then:

$$M(a) = M_a(a_c)(a - a_c) + O\left(a^2\right) \tag{3.24}$$

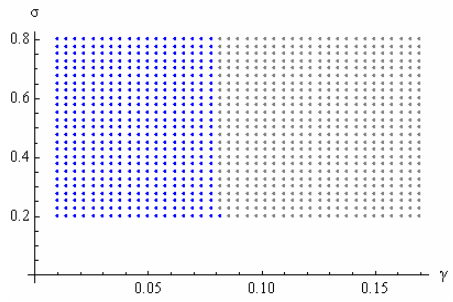

Fig.4.3 Bifurcation portrait of the supercritical Hopf bifurcation for $r = 10^{-4},\ \alpha = 10^{-4},\ \varepsilon = 10^{-3},\ m = 0.5,\ s = 1.2$. Positive sign (blue region) of the first Lyapunov coefficient at the *critical surface* $\beta_{cr} = \beta_{cr}(\gamma, \sigma)$, in the parameter plane (γ, σ) (no β_{cr} in the gray region).

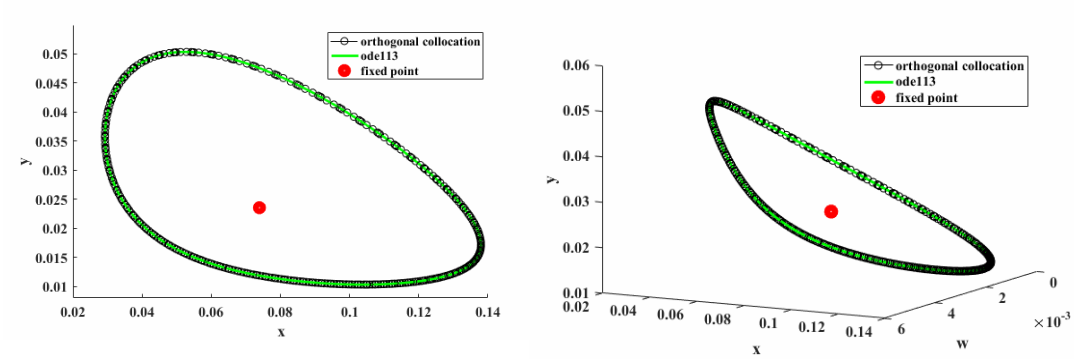
5. Bifurcation Results-Discussion

After setting $r = 10^{-4},\ \alpha = 10^{-4},\ \varepsilon = 10^{-3},\ m = 0.5,\ s = 1.2$ regarding the values of the fixed parameters, by following the procedure developed in [4] (briefly discussed in Section 3 of the present paper), we arrive at the bifurcation portrait of the system with respect to the Σ_1 equilibrium path, presented in Fig.4.3. Regarding the sign of the Lyapunov coefficient, it remains strictly negative on the whole *critical surface* $\beta_{cr} = \beta_{cr}(\gamma, \sigma)$. Thus stable limit cycles are generated through supercritical Hopf bifurcations, arising for (γ, σ) taking values in the *critical region* and $\beta < \beta_{cr}(\gamma, \sigma)$ (the real part of the complex conjugate eigenvalues

is a decreasing function of β around β_{cr} - see Section 2). Since the critical Lyapunov coefficient l_1 never becomes zero, the system undergoes solely a ***codimension 1*** Hopf bifurcation, for any critical triplet of the active parameters.

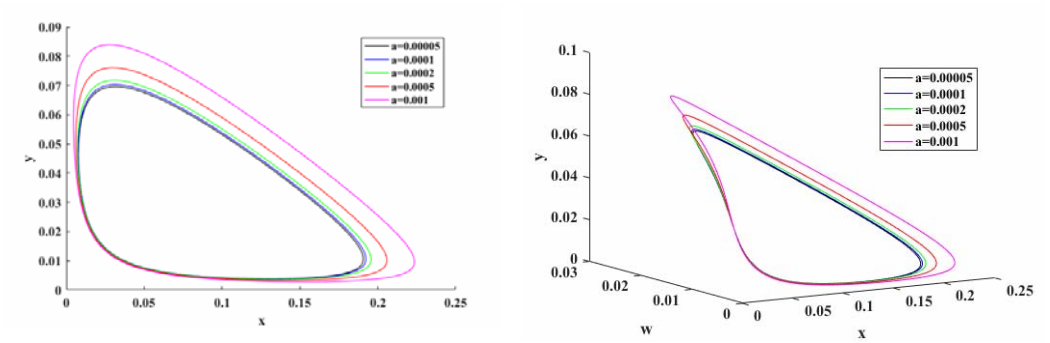


(a) **(b)**

Fig.5 (a,b) Stable cycle generated by supercritical Hopf bifurcation in xy (SI), plane and in $3D$ (SEI), respectively, for:
$(r,\alpha,\varepsilon,m,s,\gamma,\sigma,\beta)=(10^{-4},10^{-4},10^{-3},0.5,1.2,0.042,0.5,0.328525)$ ($\beta_{cr}=0.338525$), determined by a custom orthogonal collocation on finite elements algorithm. Unstable endemic equilibrium (red marker): $(x^0,w^0,y^0)=(0.073948,0.001986,0.023535)$.
Period: $T=410.572533$ days.

The fact that the limit cycles bifurcated are stable means that the phenomenon is persistent, that is the flows in a nearby neighbourhood of the limit cycle are attracted by the cycle itself, leading to the corresponding disequilibrium fluctuations defined by the periodic trajectory, as expected in a considerable number of epidemics. The bifurcation results are verified by the computation and presentation of one cycle for specific values of the parameters by use of a custom algorithm of orthogonal collocation on finite elements, shown in Figures 5 (a, b) and a family of limit cycles obtained for different values of the epidemic-induced parameter α, shown in Figures 6 (a, b), where the corresponding β_{cr} and the period T of the periodic orbits increase with α. The stability of the obtained cycles is additionally verified by numerical computation of the respective Floquet-multipliers and exponents. For the first limit cycle presented in Figures 5, the Floquet-multipliers, $\mu_i=e^{\lambda_i\cdot T}$, i=1,2,3, with $\lambda_i=(1/T)\cdot\ln(\mu_i)$ the respective exponents and T the fundamental period of the cycle, computed are: $\mu_i=\{1,0.82,1.1\times10^{-17}\}$ and $\lambda_i=\{0,-4.7\times10^{-4},-0.095\}$, respectively. Also, we note that the same cycles are generated by the variable-step, variable-order Adams-Bashforth-Moulton predictor-corrector method of orders 1 to 12, which is the standard integrated Matlab routine used to solve non-stiff ODEs, noted as "ode113" in the graphs illustrated in Figures 5 and 6.

Regarding the significance of the introduction of the additional epidemic-induced death rate, a, and the corresponding new nonlinear temrs involved in all equations of (1.3), as shown in Figures 6, it has an important effect on the numeric value of the fundamental period of the bifurcating cycles, which would have been overseen, otherwise. The introduction of "a" could also contribute in estimating the additional resources needed, based on the changes in the duration of critical phases and stages during an epidemic cycle and the maximum number of infected individuals (i.e. estimating the additional cost and health resources needed), thus making it possible to manage and control the epidemics more effectively, efficiently and with a better allocation of available resources.



(a) **(b)**

Fig.6 (a,b) Stable cycles generated by supercritical Hopf bifurcation in xy (SI), plane and in $3D$ (SEI), respectively, for:
$(r,\varepsilon,m,s,\gamma,\sigma,\beta)=(10^{-4},10^{-3},0.5,1.2,0.0548,0.24,0.46825)$, $\alpha\in[5\cdot10^{-5},10^{-3}]$, located by a custom orthogonal collocation on finite elements algorithm.
$\min\beta_{cr}=0.51825$ ($\alpha=5\cdot10^{-5}$). Periods: $T_{\min}=410.414990$ days ($\alpha=5\cdot10^{-5}$), $T_{\max}=441.550487$ days ($\alpha=10^{-3}$).

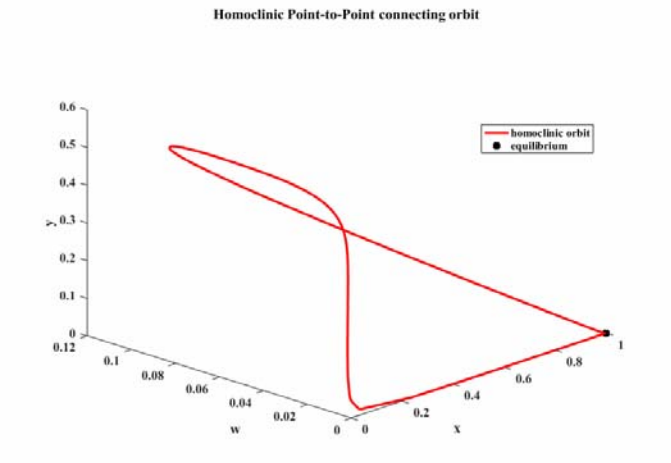


Fig. 7 Point-to-Point homoclinic orbit

Moreover, a homoclinic orbit presented in Figure 7 has been located starting from the continuation of limit cycles emerging from a Hopf bifurcation. This connecting orbit is homoclinic to a saddle endemic equilibrium located close to the disease-free equilibrium Σ_0. The significance of such an orbit is that it acts as a separatrix, as it splits the phase space in regions of qualitatively different motions; the region of oscillatory motions and the region of non-oscillatory ones. We further note that variation of the fixed parameters changes the shape and the size of the *critical* and *zero* regions, without affecting the qualitative profile of the results. In particular, increase in the rational exponents involved in the incidence rate, especially in that concerning the infective, results in a shrinkage of the *critical region*, while the *zero region*, as well as the non-equilibrium area inside that region (as regards the endemic one), expands towards lower values of the recovery rate. Last, the algorithm of orthogonal collocation on finite elements with Legendre orthogonal polynomials is proved excellent in the fast and precise numerical computation of the bifurcated limit cycles.

emails: hmora@ua.es, teresa@dtic.ua.es, jimeno@dtic.ua.es, sanchez@dtic.ua.es

Abstract

The digital transforms are intensive in multiplication and accumulation operations which have a high computational cost. Advances in computer arithmetic and digital technologies allow simplifying the processing of complex algorithms when they are implemented in modern circuits. New computation techniques can be explored to provide efficient operational methods for implementing algorithms that avoid much of the complex and costly mathematical operations. This work aims to design a high-performance paradigm for computing some common digital transforms. The proposed architecture has been implemented in a reconfigurable platform to evaluate their performance when compared to other methods. The transform used as example in this work is the Discrete Cosine Transform. The results show that the proposal offers high performance results comparable or better than best-known methods.

Key words: Digital Transform Implementation, Computational Techniques Design, Computer Arithmetic
MSC2000: 65Yxx

1. Introduction

The new capacities in circuit manufacture provided by VLSI and ULSI high-density integration methods, open up new possibilities in the design of digital transform operators. Regular circuit modelling allows compact structures and provide efficiency advantages over other methods which require complex control stages. Therefore, in this work, better calculation techniques are proposed to leverage the new technology advances. The main idea consists in designing a

direct calculation of the arithmetic expressions by means stored logic to facilitate and simplify its implementation in signal processors.

This approach could lay the basis of designing a processor core for a set of transforms. Among the wide range of signal transforms, the digital image transforms are widely used in many consumer applications. These operations have an image matrix as input to produce a result in time and/or frequency for analysis. The separable transforms adopt a simpler formulation that reduces complexity and allows the calculation of this matrix separately for rows and columns. For example, belong to this group are the known Fast Fourier Transform (FFT), Discrete Cosine Transform (DCT), Discrete Sine Transform (DST) or Discrete Hartley Transform (DHT). Their general expression is shown in (1).

$$T(u) = \sum_{x=0}^{N-1} f(x)g(x,u) \tag{1}$$

where, g(x, u) is the kernel of the transform and u ∈ 0..N-1.

2. Problem Definition

The efficient calculation of the transforms is made using the separability property. That is, the 2-D transform is organized in two consecutive 1-D transforms. This section describes the mathematical expressions from which the calculation method is proposed and defines de computation problem.

In this work, the DCT is used as example to describe how the method works due to several reasons: (a) this transform has a simple mathematical formulation but needs significant amount of computing resources; (b) it is intensely studied and a huge volume of proposals exists to compare with them; and (c) it is being part of the most common functions required by new multimedia applications [1,2].

$$F(u) = \frac{C(u)}{2} \sum_{x=0}^{7} f(x) cos\left[\frac{(2x+1)u\pi}{16}\right] \tag{2}$$

where the kernel of the transform and C(u) are:

$$g(x,u) = cos\left[\frac{(2x+1)u\pi}{16}\right] \quad C(u) = \begin{cases} \frac{1}{\sqrt{2}}, if\ u = 0 \\ 1, otherwise \end{cases}$$

Other mentioned transforms have similar computing needs.

3. Proposed Computing Architecture

The methodology uses the basic mathematical formulation of the transform described by (2). According to this expression, the calculation of each F(u) contains several multiplications and additions. The set of constants are depending of the kernel g(x, u) of the transform.

The key design features of the proposed architecture are two: (a) how multiplication and addition operations required for each F(u) are composed, and (b) how the constants C_{uj} are including in the processing of each multiplication. With regard to the first issue, (a), the standard method of calculating each multiplication operation consists of the well-known following stages [3]: partial product generation, partial product reduction and final addition. The proposed idea consists in computing the eight multiplications and seven additions of each F(u) in a combined way, so that, the partial product reductions are integrated with the additions required in each calculation. This approach allows to accelerate a variety of arithmetic operators where additions and multiplications are present. Thus, it should improve overall computation of the transform, where former operations are very frequent, instead of performing complicated designs for reducing the complexity. Regarding the constants involved (b), the proposed design avoids reiterated calculations by the direct generation of only non-zero digits of each constant. To improve the generation of partial products, we use signed-digit format to represent those constants and so minimize the number of nonzero digits while keeping the error within the *p* bits length. The next figure depicts the overall scheme of the transform calculation and the detailed generation of each F(u).

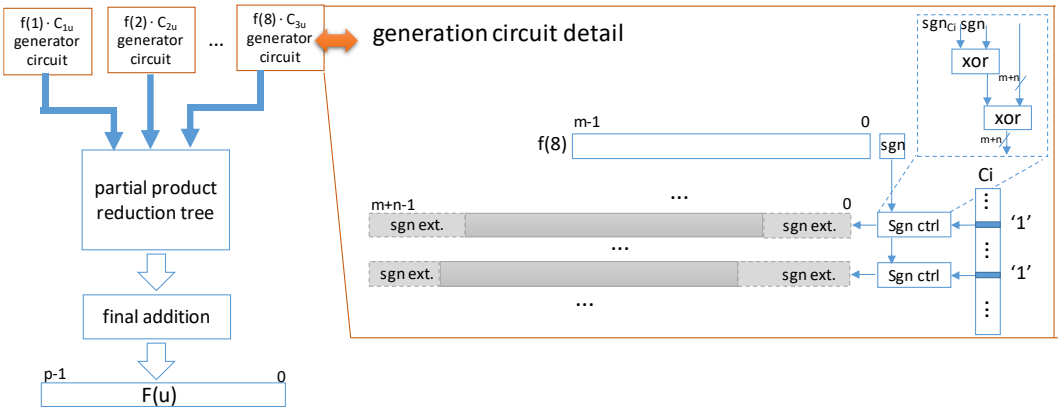

Fig. 1. Overall block diagram with direct partial product generation detail for n=8

This proposal doesn't have to compute symmetries neither decomposition operations for transform calculation to reduce the processing delay because all addition and multiplication operations involved in each F(u) are considered in an integrated way.

4. Evaluation the Performance of the Architecture

The proposal has been evaluated in term of area, delay and power consumption. A normalized balance in equality terms by using homogeneous costs of the components of the architecture is conducted to compare with other designs or proposals [4, 5]. The calculated delays correspond to the critical path of the designs, and they are set by the delay of the slowest path through the circuits.

The results of the estimations and simulations shown demonstrate that the proposal described in this research significantly reduces the execution time of other designs. Additionally, our proposal, allows a more regular structure when calculating all components of the transform in a uniform way. It therefore allows implementation of segmented or pipelined processing strategies that could reduce combined computation.

5. Conclusions

The architecture provides a compact structure for performing operations that does not require ROMs to perform multiplications. The study focus on Discrete Cosine Transform as example of the architecture for being very useful in design of embedded devices for multimedia applications. This approach doesn't need to insert precompute stages to reduce the operations involved. It has proven that a simple approach can provide good performance results.

In comparison to the existing designs, the approach offers some advantages that can be explored for high-speed calculators. We have shown that VLSI implementation through FPGA synthesis can easily meet challenging requirements for high performance applications.

A proposal for computing congestion from trajectories

Francisco Javier Moreno Arboleda[1], Simón Zea Gallego[1] and Jaime Guzmán Luna[1]

emails: fjmoreno@unal.edu.co, szeag@unal.edu.co, jaguzman@unal.edu.co

Abstract

Vehicle congestion is a problem that overwhelms the big cities. A slow segment is the part of a trajectory (i.e., a subtrajectory) where a vehicle (e.g., a taxi) is considered to have a slow movement according to an established speed limit. In this work, we propose an algorithm that identifies slow segments from the historical data of trajectories of moving objects (e.g., vehicles) and based on a formal definition of congestion that we also propose in this work.

.

Key words: congestion, trajectories, slow segments

1. Introduction

Vehicle congestion [1] is a problem that overwhelms the big cities. The negative impacts of congestion include more time for commuting (to work) and for the delivery of goods and services, more fuel consumption, more air pollution, more mortality (diseases associated with pollution), and loss of money for individuals and companies.

For example, in 2015 in Belgium the average time spent by people in traffic jams was 44 hours, and according to Martin Powell [2], a Siemens mobility expert, 1% of Europe's GDP is wasted in traffic jams, i.e., around 300 million euros.

The reduction of congestion is part of the strategic vision of the development of a city, which articulates mobility, competitiveness, human and urban growth with the sustainability of the city and its quality of life. The reduction of congestion requires multidisciplinary efforts and appropriate policies and measures.

A first step in solving the problem of congestion is to determine when a region is congested. A second step is to identify *where* (regions) and *when recurrent congestion* occurs. For example, a segment of a road where there is always congestion on business days between 7 am and 8 am. In this work, we propose an algorithm that identifies these segments (for space limitations it is not presented here but in the full paper) from the historical data of trajectories of moving objects (e.g., vehicles) and based on a formal definition of congestion that we propose in this work.

2. A Simple example

Suppose we have the annual history of the daily trajectories [3] followed by vehicles in a city. Each trajectory is made up of a set of coordinate points (latitude, longitude, and time). For simplicity, the region of analysis will be rectangular.

From each trajectory we will extract its *slow segments*. A slow segment is the part of a trajectory (i.e., a subtrajectory) where the vehicle is considered to have a slow movement according to an established speed limit (defined by the analysts). For instance, a segment of a trajectory between 7 am and 7:08 am during which the vehicle maintained a speed below 10 km/h. The slow segment must also be *maximum in duration*, so in the previous example, the speed of the vehicle must be greater than or equal to 10 km/h *immediately before* 7am or *immediately after* 7:08 am.

On the other hand, in order to analyze the congestion, the region of interest is segmented into *squares* (*a square tesselation*) with side length l (the analyst defines this value). For the identification of periods of congestion, time is also segmented. For temporal segmentation, the day is divided into n time segments each of size dt (the analyst defines this value), e.g., dt = 15 minutes. The representation of the region of interest squared in a specific time segment is called a *scenario*. Thus, for a squared region, there are n scenarios in one day.
In each scenario, the slow segments are identified. Note that a slow segment can be spread across multiple scenarios. For example, a slow segment of a trajectory between 7:12am and 7:43am is included in two scenarios (one from (7:00am to 7:15am] and the other from 7:15 am to 7:30am]). In Figure 1 we show a scenario and the slow segments in one of its squares (the square is zoomed).

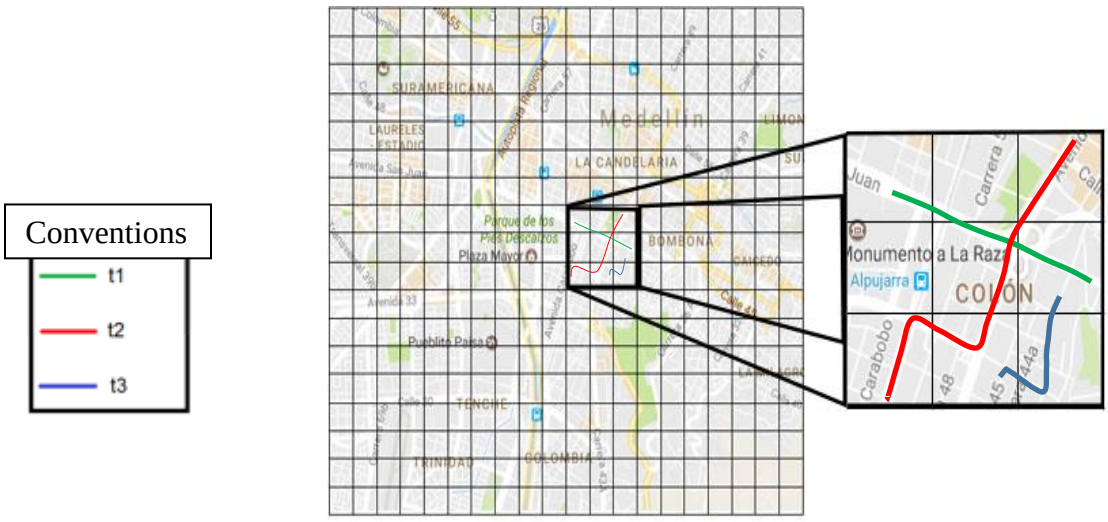

Figure 1. Scenario and square with slow segments of three trajectories.

After having identified the slow segments in a scenario, we can calculate the congestion in a square. This measure is a number between 0 and 1 and corresponds to the ratio between the total distance of slow segments in the square over the total distance of the trajectory in the square, where 0 means no congestion and 1 is the maximum congestion.

For example, consider the square of a scenario shown in Figure 2. We show in brackets the slow segments (with their corresponding distance) of two trajectories that pass through this square. There, trajectory 1 had a slow segment whose distance was 5 and trajectory 2 had a slow segment whose distance was 4. Therefore, the congestion of this square is (5 + 4) / ((8 + 5 + 10) + (10 + 4 + 8)) = 0.2.

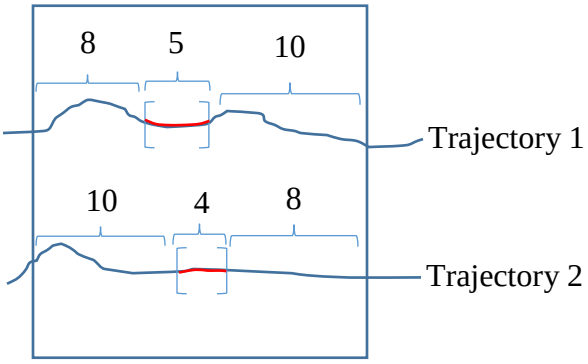

Figure 2. Square with segments of two trajectories.

After obtaining the congestion of each square, we analyze in each scenario how congestion is spread across the squares. For example, we can analyze congestion between two adjacent squares, i.e., those having one side or one point (for the case of diagonal squares) in common, during all temporal segments of the same day or every morning of the same weekday (e.g., every Monday morning or every Saturday morning) for a year.

Definition: Congestion in a square of a scenario: Let a square $R[v, w]$ of a scenario E associated with a region R of order p X q (i.e., p X q squares), $0 < v \leq p$, $0 < w \leq q$, $SL = \{sl_1, sl_2, \ldots, sl_p\}$ the set of all the slow segments of all trajectories that passed through $R[v, w]$ and $SM = \{sm_1, sm_2, \ldots, sm_k\}$ the set of all segments (whether it be slow or not) of all trajectories that passed through $R[v, w]$.The congestion of $R[v, w]$ is:
$(\sum \text{lenght}(sl_i), i = 1,\ldots,p) / (\sum \text{lenght}(sm_i), i = 1, \ldots, k)$.
Where the length() function calculates the total distance of a segment (whether it be slow or not).

Abstract

The purpose of this work is to develop a methodology based on the use of holographic tools to learn Biology and Geology contents related with cellular division. The work is thought to be carried out in the 4th course of high school education with two groups of students, one them will work in a traditional way and the other with the use of this methodology. To test is there is a significant difference between the results obtained by the two groups after having answered a questionnaire related to cell division concepts, a mean comparison test is going to be carried out. Moreover, it also intended to assess the level of motivation of student when using the methodology to evaluate its use and improvement in the future.

Keywords: Meaningful learning, Cellular division, Holographic tool, High School level

1. Introduction

The importance of science in society requires that teaching methods used in classrooms encourage meaningful learning based on competency achievement. The STEM (Science, Technology, Engineering and Mathematics) pedagogical methodology in the classroom is crucial as it aims to approach interdisciplinary learning based on project resolution.

In science learning, a high number of researches have been carried out to learn about difficulties in students [3, 4] as they negatively affect the acquisition of meaningful learning. In the case of cellular biology, the concepts of photosynthesis, respiration, genetics and cell division are the ones that present the most difficulties.

A study based on a methodology to favour the conceptual change of students, concludes that it is necessary to use three-dimensional models and referents as close as possible to the student to enhance their meaningful learning [6]. In this context, the potential of the hologram in training programs is undeniable especially in the sciences. The hologram was invented in 1947 by Dennis Gabor, who won the Nobel Prize for Physics in 1971. There have been advances in the holographic projection in the visual improvement of the technique "Ghost Pepper" that was applied in the mid-nineteenth century.

The prisms are also based on the same "Ghost Pepper" technique, with the difference that only a reflective surface is placed on top of a monitor or screen so that the image is seen on the surface. A study establishes a pedagogical foundation of how the hologram is a teaching medium considering that it is supported by the principles of general pedagogy [10]. The student has the feeling that this object is present and feels more predisposed towards learning. There are three factors that allow us to argue this fact: a) The possibility of such observation facilitates mental representation and the formation of concepts, laws, etc.; b) It allows to obtain the representations based on the relations between the form and the content; c) It strengthens the students relationships as they originate conceptual relations of an individual character and also those of the whole in the class group. Likewise, their motivational potential is projected in the possibility of generating learning contexts among equals that encourage the creation of a shared work environment [9].

Balogh *et al.* made a project in which they used different optical modules that sent light to a holographic display to show a hologram without the need for additional use of lenses [2]. Agócs *et al.* collaborator of the previous one, used diverse optical modules besides mirrors to obtain certain interactivity [1]. Jones *et al.* developed a device composed of a field light visualizer that allows human eyesight of binocular type to be able to see an image formed in 360 degrees, this is possible thanks to a high-speed projector, which transmits images to a mirror with holographic diffuser and electronic circuitry to decode digital video signals, this shows as a result a projection of the object that can be observed without the need to wear special lenses and also avoid the restriction of seeing yourself only from a reference point [7]. A study carried out with 400 teachers on the effectiveness of holograms in education. The results showed that teachers consider this technique potentially effective in achieving meaningful learning [5].

It is worth noting that the research works that refer to the use of holograms for educational purposes, derived from the collections of Serra *et al.* [10], are based on analogic or transmission holograms which are in static plates and are not in motion. It deals with interactive holographic applications through posterior projection or mobile prisms whose objective is to create interactive contents for people of both commercial and institutional applications. Another study comments about how the proper implementation of holograms in classrooms makes students see themselves submerged in a striking environment that makes them to concentrate and build their own learning from their own previous experiences [8].

2. Objectives

The general objective of the present work is to design a holographic technological tool that contributes to the meaningful learning of the students of 4th year of High School Education and to evaluate the degree of satisfaction of the same ones after the use of the tool.

3. Methodology

This study is thought to be carried out with two groups, control and experimental, in the 4th year of High School Education in the subject Biology and Geology. Firstly it will be required that students answer a pre-test to know their previous concepts and them a post-test to assess if there are significant differences between the results obtained after the application or not of the tool. Finally, a questionnaire related to the use of the tool to assess the degree of satisfaction was answered. For the work with the experimental group, after having answered the pre-test, the students have to build the holographic pyramidal prisms with polyethylene music and plastic CD cases and to make videos, both for mitosis and meiosis, taken from Youtube® and edited with the Camtasia® Video Editor. For the analysis of post-test results, a comparison of means in independent groups will be carried out so as to test if there are significant differences between them.

4. Conclusions

A methodology has been stablish for the understanding process of cell division concepts using a hologram due to the fat that this tool if thought to be better for science learning than the typical videos and animations is because it increases the degree of motivation of the students when working with it. The next step is the apply it on the classroom, firstly as a pilot study and then with a greater sample, so as to verify whether the assumptions have been achieved or not. Moreover, it is

also though to make an improvement of this tool to work with interactive holograms through the phenomena "Ghost Pepper" and "Rear Projection" in which semitransparent sheets are used to work the contents through an interface of interaction using a motion sensor as Kinect.

Multivariate conditional quantile dependence between energy prices and clean energy stock returns

Juan C. Reboredo[1] and Andrea Ugolini[2]

[1] *Department of Economics, Universidade de Santiago de Compostela, Spain*

[2] *Post Graduate program in management – PPGA, Unifacs, Brazil*

emails: juancarlos.reboredo@usc.es, andrea.ugolini85@gmail.com

Abstract

We assessed the impact of quantile energy price movements on the quantiles of clean energy stock price returns using a multivariate vine-copula dependence setup. For the period 2009-2016, our evidence shows that oil and electricity prices were major contributors to the dynamics of clean energy stock returns in the USA and the EU, respectively, whereas coal prices played a minor role in shaping clean energy stock price returns. Furthermore, we found evidence of a symmetric energy price impact, so extreme upward or downward energy price movements had a similar impact on clean energy stock returns. This evidence has potential implications for risk management decision making by energy investors and for policy maker decision making regarding support for clean energy deployment.

Key words: Energy prices; clean energy stock price returns; copulas

1. Introduction

The dynamics of energy prices is one of the main energy-related risk factors that can impact on the financial performance of clean energy investments projects, rendering the substitution of exhaustible for sustainable energy resources more or less viable on economic grounds (see, e.g., Kumar et al., 2012; Reboredo, 2015). Therefore, identifying how the dynamics of different energy prices impacts on the value of renewable energy companies is of particular interest to investors who need to assess the sensitivity of their renewable energy investments to energy prices, in particular, when energy prices are especially low or high. Policy makers are also interested in how fluctuations in energy prices shape renewable energy

stock prices as market forces driving energy prices may provide investors with market-based incentives to invest in the green energy industry, so public investment efforts could be optimally managed.

We modelled the impact of energy prices on new energy stock prices by considering the impact of different energy prices on renewable energy stock prices in a multivariate setup, in which dependence between different energy prices and renewable stock prices was measured, while taking into account direct and indirect price transmission channels. Specifically, we characterized the multivariate dependence structure between oil, gas, coal and electricity energy prices and clean energy stock prices using vine-copula models (Joe, 1996), which characterize high-dimensional joint distributions using a hierarchical structure comprised of a set of bivariate copulas that capture dependence between two variables. This empirical approach offers modelling flexibility, as marginal models and multivariate dependence structures are modelled independently; in particular, it enables the conditional quantile dependence between renewable energy price changes on energy prices — and vice versa — to be assessed, considering both direct and indirect channels of influence. Furthermore, this conditional dependence information can be used to compute the contribution of each energy price change to clean energy stock price movements.

Our empirical analysis characterized the multivariate dependence structure between clean energy stock price indices and oil, gas, coal and electricity prices in the EU and the USA for the period January 2009-September 2016. Our results indicate that the multivariate dependence structure is given by a C-vine hierarchical structure, in which electricity and oil prices play a central role in determining conditional dependence in the EU and USA, respectively. Dependence was mostly time-varying and the analysis of the quantile impact of different energy prices revealed that movements in energy prices played an important role in renewable energy price dynamics, in particular, in extreme downward or upward energy price fluctuations in the EU and the USA. Furthermore, our evidence also indicates that oil prices were the main contributor to new energy stock price movements in the USA, with coal prices playing a minor role. Gas prices played a minor role in shaping renewable energy stock prices in the EU and a more significant role in the USA. Finally, our empirical evidence reveals that the impact of energy prices on renewable energy prices was symmetric, so extreme upward or downward energy price movements had a similar impact on stock prices.

2. Methods

Let o_t, g_t, c_t and e_t be the (log) change in oil, gas, coal and electricity prices, respectively, and let r_t be the (log) change in the renewable energy stock

price. The impact of fluctuating energy prices (for oil, say) of a size given by its β-quantile on the α-quantile of the stock price return distribution for renewable energy prices, given the prices of the other energies, can be measured as:

$$P(r_t \le q^{r_t|o_t}_{\alpha,\beta,t} \mid o_t \le q^{o_t}_{\beta,t}, g_t, c_t, e_t) = \alpha, \quad (1)$$

where $q^{r_t|o_t}_{\alpha,\beta,t}$ is the conditional α-quantile for renewable energy returns at time t and where $q^{o_t}_{\beta,t}$ is the unconditional β-quantile for oil prices, which can be obtained from the inverse of their distribution functions F as:

$$q^{r_t|o_t}_{\alpha,\beta,t} = F^{-1}_{r_t|o_t \le q^{o_t}_{\beta,t},\, g_t, c_t, e_t}(\alpha), \quad (2)$$

$$q^{o_t}_{\beta,t} = F^{-1}_{o_t}(\beta). \quad (3)$$

We can thus measure the impact of oil price fluctuations of different sizes on renewable energy stock prices under different market circumstances, as given by the stock price quantiles. We can also assess the contribution of oil price movements to renewable energy prices at the α-quantile by considering the difference between the conditional and unconditional values:

$$\gamma_{o_t} = q^{r_t|o_t}_{\alpha,\beta,t} - q^{r_t}_{\alpha,t}. \quad (4)$$

where $q^{r_t}_{\alpha,t} = F^{-1}_{r_t}(\alpha)$ is the unconditional α-quantile for the return distribution. Note that when $\gamma_{o_t} = 0$, oil price fluctuations have a negligible impact on stock returns, and when $\gamma_{o_t} < 0 (> 0)$ oil price movements move stock returns in the same (opposite) direction.

Similarly, we can consider the quantile impact arising from other energy price fluctuations, namely, g_t, c_t and e_t, and compute γ_{g_t}, γ_{c_t} and γ_{e_t}. As the sum of γs is not equal to 1, we can normalize the contribution of energy price fluctuations to stock returns as:

$$\hat{\gamma}_{o_t} = \frac{|\gamma_{o_t}|}{|\gamma_{o_t}| + |\gamma_{g_t}| + |\gamma_{c_t}| + |\gamma_{e_t}|}. \quad (5)$$

Eq. (1) can now be expressed in terms of the copula function as:

$$C_{r_t,o_t|g_t,c_t,e_t}\left(F_{r_t|g_t,c_t,e_t}\left(q^{r_t|o_t}_{\alpha,\beta,t}\right), F_{o_{2t}|g_t,c_t,e_t}\left(q^{o_t}_{\beta,t}\right)\right) = \alpha\beta. \quad (6)$$

where $C_{r_t,o_t|g_t,c_t,e_t}(\cdot)$, the conditional bivariate copula between oil and renewable energy returns, can be obtained by partially deriving the copula function in Eq. (7). Next, given the values for α and β and given that $F_{o_{2t}|g_t,c_t,e_t}\left(q^{o_t}_{\beta,t}\right) = \beta$, we can solve from the copula specification in Eq. (9) to obtain $F_{r_t|g_t,c_t,e_t}\left(q^{r_t|o_t}_{\alpha,\beta,t}\right)$. We obtain $q^{r_t|o_t}_{\alpha,\beta,t}$ by inverting the conditional distribution function of r_t, which can be

obtained from the conditional copula. This procedure is also applied to the other energy prices in order to obtain their conditional quantiles.

We characterized multivariate dependence using a vine-copula, which factorizes multivariate copula density in terms of a successive mixing of 5(5-1)/2 bivariate linking copulas with a hierarchical structure (see Joe, 1997; Bedford and Cooke, 2001, 2002; Kurowicka and Cooke, 2006; Aas et al., 2009). Specifically, we considered the C-vine, D-vine and R-vine copulas given by:

$$f\left(x_1,x_2,x_3,x_4,x_5\right)=\prod_{k=1}^{5}f_k\left(x_k\right)\prod_{h=2}^{5}c_{1,h}\left(F_1\left(x_1\right),F_h\left(x_h\right)\right)\prod_{j=2}^{5-1}\prod_{i=1}^{5-j}c_{j,j+i|1,\ldots,j-1}\left(F\left(x_j\mid x_1,\ldots,x_{j-1}\right),F\left(x_{j+i}\mid x_1,\ldots,x_{j-1}\right)\right), \quad (7)$$

$$f\left(x_1,x_2,x_3,x_4,x_5\right)=\prod_{k=1}^{5}f_k\left(x_k\right)\prod_{h=1}^{5-1}c_{h,h+1}\left(F_h\left(x_h\right),F_{h+1}\left(x_{h+1}\right)\right)\prod_{j=2}^{5-1}\prod_{i=1}^{5-j}c_{i,i+j|i+1,\ldots,i+j-1}\left(F\left(x_i\mid x_{i+1},\ldots,x_{i+j-1}\right),F\left(x_{i+j}\mid x_{i+1},\ldots,x_{i+j-1}\right)\right), \quad (8)$$

$$f\left(x_1,x_2,x_3,x_4,x_5\right)=\prod_{k=1}^{5}f_k\left(x_k\right)\prod_{i=1}^{5-1}\prod_{e\in E_i}c_{j(e),k(e)|D(e)}\left(F\left(x_{j(e)}\mid x_{D(e)}\right),F\left(x_{k(e)}\mid x_{D(e)}\right)\right), \quad (9)$$

where $f(\cdot)$ denotes the density function. Marginal models in Eq. (6) are given by an average ARMA (p,q) with TGARCH components.

3. Results

We used daily data for energy prices for the USA and the EU, expressed in USD and EUR, respectively, for the period 2 January 2009-1 September 2016. The data were sourced from Bloomberg as follows: (a) for crude oil, the WTI and Brent benchmark prices for the USA and the EU, respectively; (b) for gas, natural gas futures (NYMEX) for the USA and the UK natural gas futures for the EU; (c) for coal, the Nymex Clearport Central Appalachian Coal Futures for the USA and the ARA (Argus/McCloskey) for Europe; and (d) for electricity, the NYMEX PJM Electricity futures for the USA and the Phelix index for the EU. Finally, for renewable energy prices, we used the ECO Clean Energy Index (ECO) for the USA and the European Renewable Energy Index (ERIX) for the EU.

Figures 1 and 2 depict the estimated multivariate dependence structures for the EU and the USA, respectively. In both cases, the best fit was offered by the C-vine copula structure. Electricity prices played a pivotal role in the EU, whereas

oil prices were central in the USA. Our estimates also show that the Student-t copula was the best fitting bivariate copula in most cases, indicating that symmetric dependence characterized multivariate dependence between energy price movements and clean energy stock returns.

Figure 1. Vine-copula structure for EU.

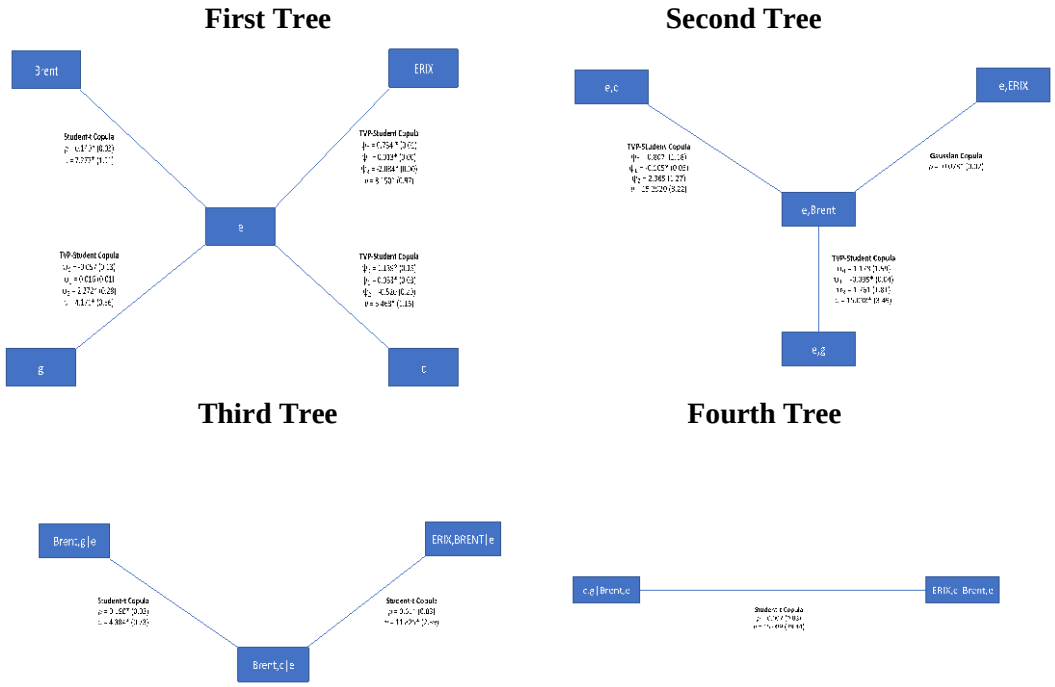

Figure 2. Vine-copula structure for the USA.

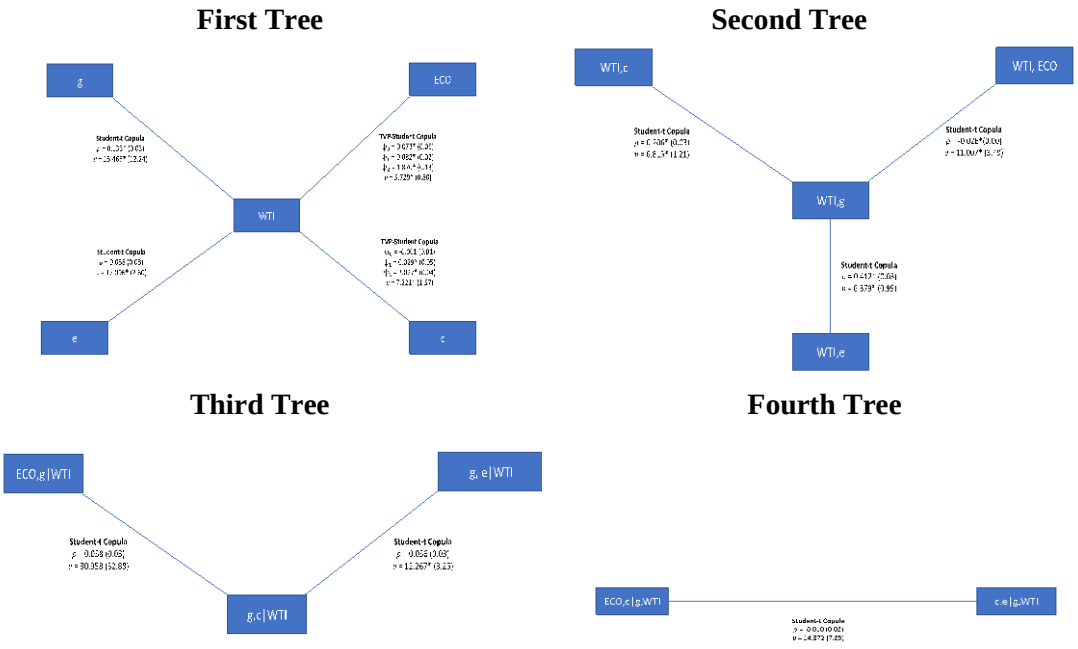

Tables 1 and 2 present empirical evidence for the contribution of energy prices to clean energy stock returns at different quantiles. This quantitative evidence confirms that: (a) the contribution of energy prices is symmetric and (b) the main contributor in the EU is electricity, whereas in the USA this role is played by oil.

Abstract

1. Background

Two models are commonly used in the estimation of hospital production function: the Cobb-Douglas and the transcendental logarithmic (Translog model). Using these models for estimation and prediction, the functional shape of continuous inputs is "forced" to follow a linear parametric form, which frequently does not fit the data closely. The relative lack of flexibility of parametric models has led to the development of non-parametric regression techniques based on the broad family of generalized additive models (GAMs).

This paper studies the use of Additive Models (AMs) to calculate hospitals production functions. The results of this new approach are compared with the Cobb-Douglas and the Translog models.

2. Data description

The variables we use consist of inputs to hospital production in the form of capital and labour, and outputs from production.

We have chosen the output of Inpatient care measured as number of admissions standardized by means of complexity, obtaining homogeneous units of production (UPHs),calculated by multiplying the number of admissions by the complexity (weight) obtained from the Diagnostic Related Groups (DRGs).

Following Ferrier and Valmanis hospital inputs are measured as follows: in terms of capital we use the average number of beds (Beds) in each hospital.

Labour inputs are measured by the number of consultant full-time equivalents (FTEs) employed in each hospital.

Workload statistics were collected by hospital, as panel data, from the Regional Ministry's Information System, for the period 2010-2016. Hospitals have been classified within three clusters by Reyes following their size: Cluster 1 (small; < 200 beds), Cluster 2 (medium; 200 − 650 beds), and Cluster 3 (large; > 650 bedts).

3. The statistical models

The Cobb-Douglas production function proposed by Charles W. Cobb and Paul H. Douglas takes the following form for our model:

$$\ln UPHs = \beta_0 + \beta_1 \ln(FTEs) + \beta_2 \ln(Beds) + \beta_4 Year + \sum_{h=1}^{nH-1} \alpha_h Hospital_h + \varepsilon. (1)$$

A standard procedure for introducing the possibility of technical change is to include a time trend (Year). This captures observed changes in the technology.

An alternative to the Cobb-Douglas production function is the translog production function. The form of translog production function used is as follows:

$$\ln UPHs = \beta_0 + \beta_1 \ln(FTEs) + \beta_2 \ln(Beds) + \beta_3 \ln(FTEs)\ln(Beds) + \beta_4 Year + \sum_{h=1}^{nH-1} \alpha_h Hospital_h + \varepsilon. (2)$$

The flexible model considered was the following AM including a Beds-by-FTEs interaction:

$$\ln UPHs = \beta_0 + \beta_1 Year + f_1(\ln FTEs) + f_2(\ln Beds) + f_3(\ln FTEs, \ln Beds) + \sum_{h=1}^{nH-1} \alpha_h Hospital_h + \varepsilon, (5)$$

where *f1* and f2 are unknown smooth functions of the number of beds (log scale) and the number of physicians (log scale) respectively, and f3 is a unknown smooth function representing the possible interaction between the number of beds and the number of physicians (both in log scale).

It should be noted that the categorical covariate 'Hospital' was also included in the previous models. In these models, *nH* denotes the number of hospitals (in our study 10), and *Hospitalh* is a dummy variable taking the value 1 for the *hth* hospital and 0 otherwise.

With regard to the estimation of the model, penalized thin plate splines were used to represent the smooth functions *f1*, *f2* and *f3*, and the optimal smoothing parameters were estimated via Restricted (or Residual) Maximum Likelihood (REML).

All the statistical analysis was performed using R software, version 2.9.1. AMs were fitted using *mgcv* package.

4. Results

In this section, we describe the results of each estimated model, for the Regional Health Service hospitals as an overall and every hospital Cluster. We evaluated the models based on the AIC (Akaike Information Criterion) and the economic interpretation for an output change due to changes in input factors.

First of all, the models have been estimated for the Regional Health Service hospitals as an overall. Related to goodness of fit for the models, both the R2 and the AIC indicate that the AM provides a better fit in comparison with the two classic models, CD and Translog.

Following the results for Cluster 1, AM regression model is the only one able to detect a significant interaction between Beds and FTEs inputs ($p = 0.041$). Paying attention to AIC (CD = 1073.084, Translog = 1072.302, AM = 875.337) and R2 values (CD = 63.41, Translog = 63.54, AM = 78.50) we could observe a higher explanation power from the AM rather than for classic ones.

Paying attention to the results for Cluster 2, the effect of interaction between input factors is captured by models translog and flexible one ($p < 0.003$). Even more, the AM model, unlike the classic ones, is able to show that changes in production technology, captured by time trends, would affect the output ($p = 0.022$). The significant hospital effect for the three models ($p < 0.001$, in all cases) seems to reflect some variability related to the size of the hospitals included in Cluster 2. As in the previous results, not only the AIC estimates but also the R2 (CD=77.68, Translog=78.32, AM=85.30) seem to show the advantage of AM behind the classic ones.

The estimation results for Cluster 3 show significant effects of Beds for the three models ($p < 0.001$) while at the same time there are not any significant effects related to FTEs, hospital and technical change (Years) variables for the CD and Translog, but the AM detects effect for the FTEs ($p = 0.037$). However, there is a significant interaction between Capital and Labour factors for the AM ($p = 0.022$) whereas there is not for the Translog ($p =0.772$). The goodness-of-fit of the AM measured by the R2 (CD=78.01, Translog=77.96, AM=86.50) as well as the AIC

(CD=775.441, Translog=777.311, AM=619.218) have been more satisfactory for the AM compared with Cobb-Douglas and Translog.

Graphical output of the results for the AMs, for the overall sample and for each hospital cluster separately, are depicted in Figure 1.

5. Discussion and Conclusions

The decision to measure production of hospitals by the AM made an attempt to improve flexibility for the functional form. The model proposed is certainly a simplified version of the complete econometric model specification (some other variables, in fact, can affect the analyzed phenomenon) but, also at this preliminary stage, the obtained results are really closed to the desirable hypotheses.

A selected set of simple indicators of production has been analyzed. These indicators have been compared across different hospital typologies. This comparative analysis gives important insights to the different variations among hospitals.

As reported in Figure 1, while medium size and small basic-care hospitals are almost homogenous in terms of bed productivity, large size hospitals presents a more complex bed productivity trend. Among hospital typologies, the AM presents a large variability for consultants' productivity. The interpretation of these results is surely an interesting instrument for decision makers in order to analyze the productive conditions of each hospital and the health care sector as an overall. Moreover, AMs may also be applied to check the classical models performance.

Results in this study suggest that AM is a promising technique for the research and application areas on health economics. Moreover, results allow to characterize the domains in which our approach may be effective like those related to demand, costs and utility functions in health care.

Key words: railway networks, routes, graphs, computer algebra systems

1. Extended Abstract

The origin of this work is a conversation with a politician of Extremadura region (Spain) about the railway network related to the region and its possible improvements. We found that there was a lack of simple tools that could help in showing different alternatives in a railway network with two different track gauges.

Two of the authors developed some years ago a complex piece of software (denoted *RutasOptiRed*) for the Spanish Railway Foundation. It evaluated best routes, precise timings, CO_2 emissions and costs for the different pieces of rolling stock of Renfe (Spanish Railways operator) running on Adif (Spanish infrastructure administrator) railway network [1,2,3]. The Spanish case is complex. The network has tracks of two gauges (standard: *1,435 mm*; and Iberian, a broad gauge: *1,668 mm*) and some double-gauge sections (with three rails). There are gauge changeovers installed at some stations, connecting both networks. Moreover, five completely different signalling systems are used in the network (ASFA, ASFA Digital, LZB, EBICAB, ETCS). Finally, some classes of

the rolling stock are dual gauge and one of them is hybrid. The performances (top speed, acceleration) of the pieces of flexible rolling stock depend on how they are working. Therefore, the problem is not trivial at all.

RutasOptiRed required complete details of all sections in the railway network as well as of all the different pieces of rolling stock. Each edge of the graph had a list of characteristics associated (like gauge, maximum speed, etc.). The existence of dual gauge sections (without a gauge changeover at their endpoints), as on the Madrid-Canfranc route, required of the development of a complex adaptation of Dijkstra algorithm [4].

That piece of software was used to study alternatives to the connection Madrid-Badajoz [5]. Soon after, the proposed connection, partially using the Seville high-sped line, was adopted by Renfe (without installing a gauge changeover, but with a guaranteed transfer), and is now still available.

It was also used to study the different alternatives to access Galicia with the opening of some parts of the new NW high-speed line and the possibilities of the new hybrid trains (Class 730) [6]. The present route is the one considered optimal by *RutasOptiRed*.

The key idea in the new approach presented here is to consider a single graph without gauge details associated to its edges. This way a standard Dijkstra algorithm can be used. Let us detail it afterwards.

Let S be the set of stations. Three undirected graphs are considered as input:

- G_1: graph corresponding to the Iberian gauge railway network (the vertices are the stations and the sections of the network are the edges)
- G_2: graph corresponding to the standard gauge railway network
- G_3: graph corresponding to the dual gauge railway network.

If a station can be reached by trains of the two gauges (either through normal tracks or double gauge tracks), it will be described by two vertices. For instance, we shall have a vertex $Zaragoza_i$ and another vertex $Zaragoza_s$ (standing for Iberian / standard, respectively). Let S_i and S_s be the sets of stations with both Iberian and standard gauges. Let $C_i \subseteq S_i$ and $C_s \subseteq S_s$ be the sets of stations where a gauge changeover is installed.

Step 1: Two new undirected graphs are considered, each one corresponding to the accessibility in each gauge:

- $G_1^* = G_1|S_i \cup G_3|S_i$ (corresponding to the sections of the network that can be traversed by an Iberian gauge train)

- $G_2^* = G_2|S_s \cup G_3|S_s$ (corresponding to the sections of the network that can be traversed by a standard gauge train)

where $G_x|S_y$ represents exchanging in graph G_x the name of all vertices, v, such that $v_y \in S_y$, by v_y.

Step 2: The two previous graphs are merged and the connectivity between the two graphs is given by the gauge changeovers positioning (Figure 1):

$$G^* = G_1^* \cup G_2^* \cup \{\{v_i, v_s\} : v_i \in C_i,\ v_s \in C_s\}$$

Observe that the elements of the last set in the formula above are of the form $\{Zaragoza_i , Zaragoza_s\}$.

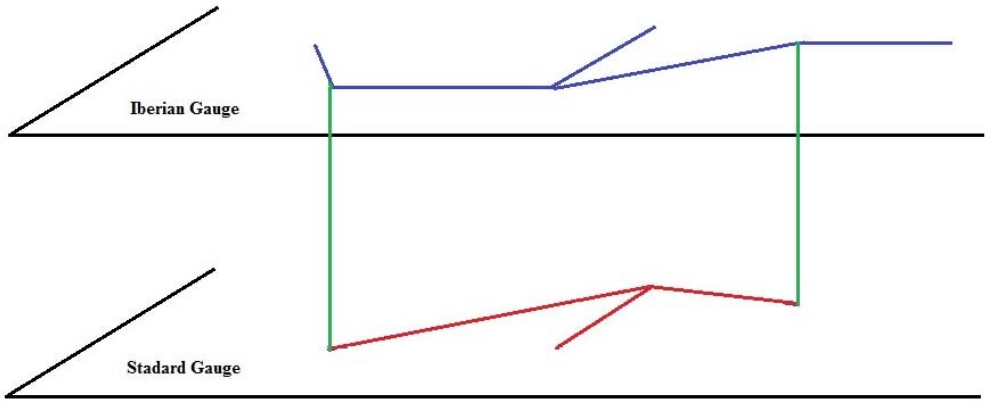

Figure 1: Graph G^* representing the global accessibility.

This way, only the real or theoretical timings have to be assigned to each edge of G^*. Edges correspond to sections of railway line or to gauge changeovers, and endpoint to endpoint timings can be easily computed. Let us note that the purpose of this new piece of software is far simpler than that of *RutasOptiRed*, although the approach for merging the subnetworks of different gauges is much simpler.

The new package is implemented in Maple, using its graphs package, and will be exemplified by analysing the Madrid–Badajoz and Badajoz–Lisbon routes, based on present and historically available lines [7,8].

Abstract

This paper presents an approach for the linguistic description of time series based related to human behaviour based on Fuzzy Deformable Prototypes. The main purpose is to create a complex behaviour model that allows to offer recommendations regarding the current situation and predictions. It is also presented a case of study based on data captured by a time-tracking tool.

Key words: Fuzzy Deformable Prototypes, Time Tracking Logs

1. Introduction

Nowadays, there is a proliferation of tools, devices and applications that allow to capture data of people activity, but, merely offer the possibility of its visualization. The integration of the available information and its subsequent analysis using intelligent algorithms would give the possibility of offering personalized services to the user. The main problem to be addressed when trying to analyse these data sources lies in the inherent inaccuracy in the recording process. With the aim of handling data of these characteristics, Fuzzy Logic [1] offers mechanisms that allow to introduce expert knowledge and formalize the uncertainty that exists on the subject. For this purpose, our proposal is based on the use of fuzzy logic techniques such as Fuzzy Deformable Prototypes [2] that allow not only the description of the phenomena but inferences to be made about the presented situations.

2. Linguistic description of human behaviours using fuzzy deformable prototypes

The use of "ideal descriptions" for human behaviours has several shortcomings. Ideal descriptions prototypically describe a fact, but in fact only approximate the ideal to a degree. Common description sentences show uncertainty or vagueness associated to the fulfilment of this ideal. Then, in the context of description, a fact or a set of facts is associated with a paradigm so that the paradigm interprets the behaviour. Thus, it is possible to describe the behaviour according to this interpretation. To generalize, many of the descriptions depend on the way the most similar paradigm or prototype for the circumstances of the problem is found.

Fuzzy Deformable Prototypes (from now on FDPs) can provide an adequate formal framework for working with this idea. FDPs come from the confluence of two approaches to the concept of prototype: the "deformable prototype" of Bremermann [3] ("*a real element is classified according to the minimum energies required for physically deforming the closest prototype"*) and the fuzzy prototypes of Zadeh [4] ("*a fuzzy prototype is a reunion of good, bad and borderline elements of a category*"). The definition of FDPs inherits some features of Zadeh's fuzzy prototype approach but includes some extensions to manage the complexity of real-world problems. For example, in FDPs there are many prototypes of a behaviour depending on its relevant features. This work uses the concept of fuzzy deformable prototypes (FDPs) in order to model different phenomena related to human behaviour.

The principle to obtain a fuzzy deformable prototype of a population of elements (for example, time segments) is to stratify it by grouping them sharing the same membership degree. For each level of stratification, the fuzzy prototype is obtained using an iterative process of clustering. During the iterative process, an object maximally summarized from each level of clustering is obtained which can be viewed as a fuzzy prototype. Where the number of prototypes for a behaviour is given, it may be meaningful to compute the collective properties of the prototypes and consider them as the reference for the corresponding descriptions and recommendations.

In addition, each fuzzy prototype can also be represented as fuzzy sets. It means that it is possible to calculate a membership degree between an element and the fuzzy set. The use of FDP's allows to evaluate new situations from these patterns, to deform [4] the most similar prototypes to this new behaviour and describe it using a combination of prototypes with the membership degrees as coefficients.
As as result of this process, we can obtain some sentences to describe the behaviour with different degrees of typicality. For example, we can use the prototypical way to describe the situation, or show some uncertainty or vagueness or show higher and lower relationships with the prototypical behaviour.

3. Case of Study: Personal Time Logs

Nowadays, tracking time is a relevant topic because it is directly related to efficiency and productivity. For this purpose, it is important to find a way to realistically and practically analyse the use of time.

Following the theory of prototypes of Zadeh [2], the concept of a time segment with respect to its productivity can include a set of prototypes, which represent the good, low or medium compatibility of the instances with the concept.

The first step of our analytics process to discover these prototypes is to calculate the behavioural features from the data provided by Time Tracking Tool. For this purpose, we analyse all relevant historic records and perform the aggregations that feature definition demands—for example, aggregating the amount of interruptions this user spent during that time segment.

Then, the following step is detecting the relationships between the different time segments and thus to obtain the fuzzy deformable prototypes based definition of them. With this aim, first a clustering process is performed based on the features previously defined. Subsequently, aggregation functions are applied on each type of time segments to calculate the features values that will define each of the prototypes. Finally, each of these prototypes is represented using fuzzy numbers.

From these definitions, we try to simulate the capacity of interpretation of the situation, that is, to find the model of evolution of productivity more adapted to the real circumstances. To this end, the user is first asked the real value of the factors that a priori determine the progression of a time segment. Their combination will give a degree of compatibility with prototypes, those prototypes with a degree of non-zero compatibility will be modified to give rise to the characterization of the time segment by a combination whose coefficients are the degrees of compatibility previously obtained.

Specifically, the system describes the situation based on the level of stress of the user. To do this, it calculates the current stress state of the user by dividing for each prototype the stress curve [5] in five stages: start, up, top, down, end. Identifying within the prototype the phase in which the user is, through a finite state machine, can be generated the linguistic description of the situation and therefore recommendations from it. In addition, the linguistic description is enriched by the characteristics of the use of time (“maker”, “manager”, “mixture”). The description provided to the current time segment would be valid if there are no influence of *local factors*. In this case, it is mandatory to modify any description or recommendation.

4. Conclusions and Future Work

Continuous analysis of time series captured from human activity allows us to describe changes in the people behaviour and offer recommendations. Fuzzy Deformable Prototypes of time segments show the different behavioural possibilities. Subsequently, each time segment type goes through a "deformation process" until a prototype match is achieved. The better we can describe the "time segment" during any window time, the easier it becomes to offer specific recommendations and predictions.

It would be interesting in future work to devise a version of the analysis in which reinforcement learning could play an important role. For example, the user's opinion about the descriptions and recommendations provided by the system can be fed back the application with this knowledge.

Abstract

A model has orthogonal block structure if it has variance-covariance matrix that is a linear combination of known pairwise orthogonal orthogonal projection matrices that add to the identity matrix. When the orthogonal projection matrix on the space spanned by the mean vector commutes with the orthogonal projection matrices, in the expression of the variance-covariance matrix, the model has commutative orthogonal block structure. Resorting to B-matrices we present a general condition for this commutativity.

Key words: B-matrices, mixed models, models with commutative orthogonal block structure
MSC2000: AMS Codes (optional)

1. Introduction

Linear mixed models are a powerful tool for analysing experimental data from several areas, such as agriculture, biology, medicine or industry. In the framework of the design of experiments in agricultural trials, in 1965, a special class of linear mixed models as emerged, called models with orthogonal block structure, OBS, based on the structure of the variance-covariance matrix [6,7]. Later on, in order to obtain optimal estimation for variance components of blocks and contrasts of treatments, using the algebraic structure of OBS, arose a particular case of these models, those of models with commutative orthogonal block structure, COBS [4].

2. Models with commutative orthogonal block structure

Let us consider a mixed model

$$\boldsymbol{Y} = \sum_{i=0}^{w} \boldsymbol{X}_i \boldsymbol{\beta}_i$$

where $\boldsymbol{\beta}_0$ is fixed and $\boldsymbol{\beta}_1$, ... , $\boldsymbol{\beta}_w$ are independent random vectors with null mean vectors, variance-covariance matrices $\sigma_1^2 \boldsymbol{I}_{c_1}$ ... $\sigma_w^2 \boldsymbol{I}_{c_w}$, where $c_i = rank(\boldsymbol{X_i}), i = 1, \dots, w$ and null cross-covariance matrices.

$\boldsymbol{Y}$ has mean vector

$$\boldsymbol{\mu} = \boldsymbol{X}_0 \boldsymbol{\beta}_0$$

and variance-covariance matrix

$$\boldsymbol{V}(\boldsymbol{\theta}) = \sum_{i=1}^{w} \sigma_i^2 \boldsymbol{M}_i$$

where $\boldsymbol{M}_i = \boldsymbol{X}_i \boldsymbol{X}_i^T, i = 1, \dots, w$.

Since the space spanned by the mean vector is $\Omega = R(\boldsymbol{X}_0)$, the orthogonal projection matrix, OPM, on Ω, is $\boldsymbol{T} = \boldsymbol{X}_0 (\boldsymbol{X}_0^T \boldsymbol{X}_0)^+ \boldsymbol{X}_0^T = \boldsymbol{X}_0 \boldsymbol{X}_0^+$, where $+$ indicates Moore–Penrose inverse.

When the matrices $\boldsymbol{M}_1, \dots, \boldsymbol{M}_w$ commute, they generate a commutative Jordan algebra of symmetric matrices, CJAS,A. This is a linear space constituted by symmetric matrices that commute and containing the squares of their matrices [5]. The CJAS, A, as one unique basis, called the principal basis, Q, that is constituted by known pairwise orthogonal orthogonal projection matrices, POOPM, [8] thus the matrices $\boldsymbol{M}_i, i = 1, \dots, w$ are linear combinations of the matrices of the CJAS principal basis

$$\boldsymbol{M}_i = \sum_{j=1}^{m} b_{i,j} \boldsymbol{Q}_j$$

With $\gamma_j = \sum_{i=1}^{w} b_{i,j}\, \sigma_i^2,\ j = 1, \ldots, m,$ the canonical variance components, the variance-covariance matrix of $\boldsymbol{Y}$ will take the form

$$\boldsymbol{V} = \sum_{j=1}^{m} \gamma_j \ \boldsymbol{Q}_j$$

Since $\sum_{i=1}^{w} \boldsymbol{M}_j \in$ A is invertible, A is a complete CJAS and $\sum_{j=1}^{m} \boldsymbol{Q}_j = \boldsymbol{I}_n$.

So

$$\boldsymbol{Y} = \sum_{i=0}^{w} \boldsymbol{X}_i \boldsymbol{\beta}_i$$

is a model with orthogonal block structure, OBS. These models, introduced in [6,7], have been intensively studied and play a central part in the theory of randomized block designs, see, e.g., [1,2].

An important class of OBS, models with commutative orthogonal block structure, COBS, arises when T, the OPM on the space spanned by the mean vector, commutes with the POOPM $\boldsymbol{Q}_j$, $j = 1, \ldots, m$. [4]. So $\boldsymbol{T}$ and $\boldsymbol{V}$ commute and the least square estimators, LSE, for estimable vectors, will give BLUE (best linear unbiased estimators) whatever the variance components [10].

Assuming the rows of $\boldsymbol{X}_0$ to correspond to the sets of levels of the fixed effects factors, the mean values of the observations will be determined by those sets.

Let us consider that there will be $\dot{n}$ sets of the levels associated to $r_1, \ \ldots, \ r_{\dot{n}}$, contiguous rows of $\boldsymbol{X}_0$. If the components of $\boldsymbol{\beta}_0$, $\beta_{0,1}, \ \ldots, \beta_{0,\dot{n}}$, are the corresponding mean values, we can reorder the observations to have the block diagonal matrix

$$\boldsymbol{X}_0 = D\left(1_{0,1}, \ldots, 1_{0,\dot{n}}\right)$$

So the orthogonal projection matrix on , the space spanned by the mean vector, is given by

$$\boldsymbol{T} = D\left(\frac{1}{r_1} J_{r_1}, \ldots, \frac{1}{r_{\dot{n}}} J_{r_{\dot{n}}}\right)$$

where $J_r = 1_r\ 1_r{}^T$

The fundamental partition of $\boldsymbol{Y}$ will be constituted by the sub-vectors $\boldsymbol{Y}_1, \ldots, \boldsymbol{Y}_{\dot{n}}$, corresponding to the $\dot{n}$ sets of the levels of the fixed effects factors [3]. Then the variance covariance matrix can be defined by

$$\boldsymbol{V} = \begin{bmatrix} \boldsymbol{V}_{1,1} & \cdots & \boldsymbol{V}_{1,\dot{n}} \\ \vdots & & \vdots \\ \boldsymbol{V}_{\dot{n},1} & \cdots & \boldsymbol{V}_{\dot{n},\dot{n}} \end{bmatrix}$$

with $\boldsymbol{V}_{l,l}$ the variance-covariance matrix of $\boldsymbol{Y}_l$, $l = 1, \ldots, \dot{n}$, and $\boldsymbol{V}_{l,h}$ the cross-covariance matrix of $\boldsymbol{Y}_l$ and $\boldsymbol{Y}_h$, $l \neq h$.

Since

$$TV = \begin{bmatrix} \frac{1}{r_1} J_{r_1} \boldsymbol{V}_{1,1} & \cdots & \frac{1}{r_1} J_{r_1} \boldsymbol{V}_{1,\dot{n}} \\ \vdots & & \vdots \\ \frac{1}{r_{\dot{n}}} J_{r_{\dot{n}}} \boldsymbol{V}_{\dot{n},1} & \cdots & \frac{1}{r_{\dot{n}}} J_{r_{\dot{n}}} \boldsymbol{V}_{\dot{n},\dot{n}} \end{bmatrix} \text{ and } VT = \begin{bmatrix} \boldsymbol{V}_{1,1} \frac{1}{r_1} J_{r_1} & \cdots & \boldsymbol{V}_{1,\dot{n}} \frac{1}{r_1} J_{r_1} \\ \vdots & & \vdots \\ \boldsymbol{V}_{\dot{n},1} \frac{1}{r_{\dot{n}}} J_{r_{\dot{n}}} & \cdots & \boldsymbol{V}_{\dot{n},\dot{n}} \frac{1}{r_{\dot{n}}} J_{r_{\dot{n}}} \end{bmatrix}$$

the matrices T and V commute if and only if

$$\begin{cases} \frac{1}{r_1} J_{r_1} \boldsymbol{V}_{1,1} = \boldsymbol{V}_{1,1} \frac{1}{r_1} J_{r_1} & \cdots & \frac{1}{r_1} J_{r_1} \boldsymbol{V}_{1,\dot{n}} = \boldsymbol{V}_{1,\dot{n}} \frac{1}{r_1} J_{r_1} \\ \vdots & & \vdots \\ \frac{1}{r_{\dot{n}}} J_{r_{\dot{n}}} \boldsymbol{V}_{\dot{n},1} = \boldsymbol{V}_{\dot{n},1} \frac{1}{r_{\dot{n}}} J_{r_{\dot{n}}} & \cdots & \frac{1}{r_{\dot{n}}} J_{r_{\dot{n}}} \boldsymbol{V}_{\dot{n},\dot{n}} = \boldsymbol{V}_{\dot{n},\dot{n}} \frac{1}{r_{\dot{n}}} J_{r_{\dot{n}}} \end{cases}$$

Which occurs when the matrices $\boldsymbol{V}_{l,h}$, $l = 1, \ldots, \dot{n}$, h= $1, \ldots, \dot{n}$ are B-matrices, see, e.g. [9], this is, when

$$\frac{1}{\dot{n}} \sum_{l=1}^{\dot{n}} \boldsymbol{V}_{l,h} = \frac{1}{\dot{n}} \sum_{h=1}^{\dot{n}} \boldsymbol{V}_{l,h} = \frac{1}{\dot{n}\dot{n}} \sum_{l=1}^{\dot{n}} \sum_{h=1}^{\dot{n}} \boldsymbol{V}_{l,h}$$

With

$$V = D\left(\sigma_1{}^2\ I_{r_1}, \ldots, \sigma_{\dot{n}}{}^2\ I_{r_{\dot{n}}}\right)$$

matrices T and V commute.

With this commutativity condition $\boldsymbol{Y}$ will be a model with commutative orthogonal block structure (COBS) and, according to the version of the Gauss-Markov theorem in [10], the LSE for estimable vectors will be BLUE.

From Graphene to Graphyne, Fullerenes, Fulleroids, Gaudienes and their Golden Duals

Peter Schwerdtfeger[1]

[1] *Centre for Theoretical Chemistry and Physics, The New Zealand Institute for Advanced Study,*
Massey University (Albany Campus), Auckland, New Zealand

email: peter.schwerdtfeger@gmail.com

Abstract

Graphene is a material with many potential applications. For example, we can introduce nano-holes into graphene membranes for the design of efficient molecular sieves. Our research group has recently succeeded to efficiently separate He-3 from He-4 by quantum tunneling.

Graphene can also be wrapped around a sphere to form fullerene structures. 12 pentagons have to be however introduced to satisfy Euler's polyhedral formula [1,2]. Graphene can also be modified to graphyne by vertex insertions. From this one obtains new fullerene structures called gaudienes. Such structures can be explained using topology and graph theory which form the basis of our general-purpose computer program Fullerene that creates accurate 3D structures for any fullerene isomer. It also creates dual structures corresponding to a triangulation of a sphere. Such a dual structure has recently been found experimentally in Lai-Shang Wang's group at Brown University, and consists of 16 gold atoms on a sphere. These unique triangulations of a sphere related to fullerene duals have exactly 12 vertices of degree five. The icosahedral hollow gold cages previously postulated are related to halma transforms of C_{20}. This dual mapping also relates the (chiral) gold nanowires observed to the (chiral) carbon nanotubes. In fact, the Mackay icosahedra well known in gold cluster chemistry are related to the dual halma transforms of the smallest possible fullerene C_{20}.

Abstract

This paper explores the efficacy of a population-based approach such as genetic algorithms in the field of feature selection, although these algorithms were created as an alternative to optimization methods like EVOP or simplex. A framework called Correlation-based Feature Selection guided by a Genetic Search algorithm (CFS-GeSe) was introduced. The results are promising especially for C4.5 classifier, bearing in mind the accuracy and Roc measures.

Key words: supervised machine learning, feature selection, genetic algorithms, data mining, dimensionality reduction.

1. Introduction

A possible taxonomy of classifiers could distinguish between different kinds of algorithms [1]. The most well-known methods fall into the category of decision trees, rule-based classifiers and black-box methods. Some pros and cons characterise every type of approach. Nowadays the available information is continuously making some progress and every second more data to be processed increases. We speak of attribute [2] or feature as the description of some existing measure in the universe that takes values in a certain domain. On the other hand, we talk about domain as the set of values of the same type. That features are taken from the data mining. The data mining [3] contains a lot of data that are treated to

be converted in knowledge. This knowledge is taken when the features are treated with or without the genetic algorithms.

Therefore, machine learning-techniques and data mining were developed to discover knowledge and recognize patterns from these data. What is more feature selection is almost a mandatory task in most of application domains in order to minimize redundancy and maximize relevance to the target, as the data collected is usually associated with a high level of noise.

2. Feature selection and genetic algorithms

Feature selection could be defined as the way to get the most relevant attributes, deleting those who are redundant or not relevant, for to obtain the most optimal result. When feature selection is applied, we get less data, greater accuracy, simpler results and less attributes; for this reason, the efficiency is increased and the accuracy and the understanding of the results [4].

The only way to guarantee the optimal selection of this final subset is to do an exhaustive search of all the possible subsets. However, this could take a long time as for N features the number of possible subsets is 2^N. The purpose of feature selection is to select a subset of the most relevant features out of the larger set, maximizing the classification performance. In other words, those features which are highly correlated with the class [5].

Genetic algorithms are based on natural evolution, identifying the attribute as chromosome, and the parts of the attribute as genes. This evolution is based on the idea that the chromosomes with "good structures" survive more likely.

There are several ways to obtain these attributes to make the selection (randomly, by tournament, according to their evaluation,...), but the genetic algorithms [6] make it favouring the best while allowing the diversity. This diversity is obtained by giving all the genes a probability of being chosen, so that although the best is favoured, one with less probability can be part of the gene that allows us to obtain the most optimal result. The methods used [7] in genetic algorithms are based on mutations or crossings of genes through which the best attributes are obtained. While permutations are crosses based in cycles, crossings exchange chromosome segments.

The most commonly used technique in feature selection is the stepwise approach [8], which can run forward or backward. In the forward version, the variables are selected and added to the model one at time, until no improvement in the results is obtained. In the backward version, the first model to be computed is the one with all the variables; the variables are then selected and removed one at time. A mix of these two approaches is also used, in which each addition of a variable by the forward selection is followed by a backward elimination. The stepwise techniques have two main disadvantages: first, each choice heavily affects the following choices; and second, the final result is expressed by a single combination, and then no choice is given to the user.

Genetic algorithms, in their favour, always allow the exploration of the whole experimental space: due to the occurrence of the mutations, each possible combination can occur at any moment. The result obtained with genetic algorithms is a whole population of solutions: the user can then choose the one he prefers, taking into account at the same time the response and the variables are used. From this it is also evident that a relevant feature of genetic algorithm is the ability to detect several local maxima.

In short, data mining contains those data that which we can do a feature selection without genetic algorithms, but of course, the use to this type of algorithms give us the better features with a minimal time.

Our proposal considers a genetic search (GS) in conjunction with an attribute evaluator based on correlation known as CFS (Correlation-based Feature Selection). In a first step CFS [9] is applied to get the assessment of the features according to a correlation measure; after that a genetic search algorithm guides the search following a metaheuristic approach. The framework has been called CFS-GeSe that stands for Correlation-based Feature Selection guided by a Genetic Search algorithm.

3. Experimentation

Table 1 summarises the main parameters of the CFS-GeSe framework along with their numerical values. It is very outstanding to stress that a preliminary experimental design was carried and after that we chose the values described due to a good performance; cross validation procedure using the train set to create preliminary train and preliminary test sets. It is straightforward that these values may not be the optimal ones but were the result of a previous experimentation.

Parameter	Value
Population size	200
Number of generations	20
Probability of crossover	0.6
Probability of mutation	0.033

Table 1: Parameter values for CFS guided by a Genetic Search algorithm (CFS-GeSe).

Table 2 represents the data set used throughout the experimentation. They come mostly from binary and multi-class supervised machine learning real-world problems available in the public repository from the University of California at Irvine (UCI). We have also included the number of selected features for the proposal coined as CFS-GeSe with the training set. Last row shows the dimensionality reduction on average over the original data sets.

Data set	#Samples	#Train	#Test	#Features	#Classes	#Selected(CFS-GeSe)
Hepatitis	155	117	38	19	2	10
Ionosphere	351	263	88	33	2	12
Labor	57	43	14	29	2	9
Promoter	106	80	26	58	2	20
Waveform	5000	3750	1250	40	3	12
Average	1133.80	850.60	283.20	35.80	2.20	12.60
Dim. Reduction						64.80

Table 2: Summary of the test-bed and features selected for CFS-GeSe proposal.

Concerning the classifiers, C4.5 and BayesNet were applied to every problem a) with the original data set and b) also after the data preparation over the train set took place and the list of selected attributes were projected onto the initial sets to get the reduced train and test subsets, respectively. As evaluation measures we have included in the forthcoming tables Accuracy and Roc in the test set.

Table 3 reports the test results obtained with C4.5 classification algorithm. By rows, we have represented a concrete result in boldface meaning that the current proposal overcame the situation will all the features. If no value is in bold, no improvements happened and the single advantage of the new proposal for this problem is that a reduction in the number of features took place, arising therefore a trade-off between the computational time and the performance. From the point of view of accuracy, CFS-GeSe gets better results in two out of the five problems tested. Moving to Roc measure, three data sets take advantage of the new proposal. In both cases, the averages are also higher which accompanied to the improvements in individual results indicate that CFS-GeSe is very appropriate for C4.5 algorithm.

Data set	Accuracy		Roc	
	Original	CFS-GeSe	Original	CFS-GeSe

Table 3: Test results with C4.5 classifier.

Table 4 shows the accuracy and Roc results via the BayesNet supervised machine learning approach. We have followed the same conventions aforesaid for

the Table 3. Now, sometimes punctual enhancements happen. In other cases worst results are obtained which is enough to be very careful with the application of CFS-GeSe in combination with BayesNet. These experiments encourage to test with different feature selection approaches or even measures or kinds of searches to guide the exploration and exploitation with the findings of the first stage of the feature selection procedure.

4. Conclusions

This paper introduced CFS-GeSe which is a Correlation based Feature Selection guided by a Genetic Search algorithm. Experiments revealed that CFS-GeSe is very suitable for C4.5 classifier letting to get better test results with Accuracy and Roc measures. On the other hand, for BayesNet is not very clear that the combination with CFS-GeSe is a handy symbiosis and other ways of feature selection should be explored or even to analyse the measures, if any, that could be convenient to this very powerful supervised machine learning algorithm.

Abstract

In this work,we develop a new two-step method given by Ren et al.(2009).It includes three parameters.We approximate these parameters and increase the convergence order from 4 to 8. convergence analysis along with numerical illustrations are provided to justify and accomplish theoretical and practical aspects of the proposed methods.

Key words: Nonlinear equation, Newton's interpolatory polynomial, adaptive with memory method,R-order convergence,self accelerating parameter.

1. Introduction

Finding the root of a nonlinear equations or systems is an interesting task in numerical analysis and applied mathematics, which has attracted so much attention recently. In the last years, iterative techniques have been applied in many diverse fields as economics, engineering, physics, dynamical models,and so on.Newton's method is the most well-known method for solving nonlinear equations[1].However,the existence of first derivative is compulsory for the convergence of Newton's method, which bounds its applications in practice. To overcome on this difficulty,Steffensen replaced the first derivative of the function in the Newton's iterate by forward finite difference approximation[2].Both the methods possess the quadratic convergence and the same efficiency but second one is derivative free. Multipoint iterative methods for solving nonlinear equations are of great practical importance since they overcome theoretical limits of one-point methods concerning the convergence order and computational efficiency [2-11]. In the case of multipoint without memory methods,this requirement is closely connected with results of Kung and Traub [3],who conjectured that the order of convergence of any multipoint method without memory, consuming n + 1 function evaluations per iteration, cannot with this property are usually called optimal order.The exceed the bound 2^n.Multipoint methods recent past,researchers have focused on optimizy the existing non-optimal iterative methods without any additional evaluation of functions and derivatives.Let m_k represent the r+1 quantities x_k, $t_1(x_k)$, $t_2(x_k)$, ..., $t_r(x_k)$ and define an iterative process by $x_{k+1} = F(m_k; m_{k-1}, m_{k-2}, ...,$

m_{k-r}).Following Traub's terminology [4], F is called a multipoint iterative function with memory. To compare iterative methods theoretically, Ostrowski [5] introduced the idea of efficiency index and given by $d^{1/n}$, where d is the order of convergence and n is the number of function evaluations per iteration. In this paper we present an improvement of the existing with memory family Ren et al [6], constructed by introducing two more iterative parameters which are calculated with help of Newton's interpolatory polynomial of different degrees. In Section 2, a family of two-point methods without memory with improved order of convergence from 4 to 8 without adding more evaluations is presented.The comparisons of absolute errors and computational efficiencies are given in Section 3 to illustrate convergence behavior.Finally,we give the concluding remarks.

2. New modified three- parametric methods

In this section, we deal with modifying two-point without memory method by Ren et al [6].Its error equation has three accelerator elements.Ren et al method has the iterative expression

$$y_k = x_k - \frac{f\ x_k}{f\ x_k, y_k}\ , w_k = x_k + f\ x_k\ \ , \beta \in \mathrm{R}$$

$$x_{k+1} = y_k - \frac{f\ y_k}{f\ x_k, y_k\ + f\ y_k, w_k\ - f\ x_k, w_k\ + \beta\ y_k - x_k\ \ y_k - w_k} \quad (2.1)$$

To transform (2.1) in a method with memory, with three accelerators, we consider the following modification of (2.1) [11].

$$y_k = x_k - \frac{f\ x_k}{f\ x_k, y_k\ + pf[w_k]}\ , w_k = x_k + \gamma f\ x_k\ \ , \qquad (2.2)$$

$$x_{k+1} = y_k - \frac{f\ y_k}{f\ x_k, y_k\ + f\ y_k, w_k\ - f\ x_k, w_k\ + \beta(y_k - x_k)(y_k - w_k)}$$

where $\gamma\ \neq 0, \beta$ and p are arbitrary parameters.In what follows, we present the error equation of (2.2).

Theorem 2.1 Let $I\ \subseteq\ R$ be an open interval, $f: I \to R$ our times continuously differentiable and let αϵI be a simple zero of f. If the initial point x_0 is sufficiently close to α, then the method defined by (2.2) converges to α with order four. Moreover, the error equation is

$$e_{k+1} = \frac{1 + \gamma f l a\ ^2 (p + c_2)(\beta + f l a c_2\ p + c_2\ - f l a c_3)}{f l a} e_k^4 + O\ e_k^5 \qquad (2.3)$$

where $c_k = \frac{f^{\,k}(\alpha)}{k! f'(\alpha)}\ \ for\ k = 2,3, \ldots.$

It must be noted that schemes (2.1) and (2.2) are still methods without memory.In the next section, we discuss how they can be transformed in methods with memory with higher order of convergence without increasing the number of functional evaluations per step.

3. The development of a new method with memory

This section concerns with extracting a new method with memory from (2.2) by using three self-accelerating parameters. Theorem 2.1 states that modified method (2.2) has convergence order four if $\gamma \neq \frac{-1}{f'\ \alpha}$, $p \neq -c_2$ and $\beta \neq$ fla c_3 Now, we pose some questions: Is it possible to increase the convergence order of this method? If so, how can it be done and what is the new convergence order? For answering these questions, we look at the error equation (2.2).
It can be seen that if we set $\gamma = \frac{-1}{f'\ \alpha}$, $p = -c_2 = -\frac{f''\ \alpha}{2f'\ \alpha}$ and $\beta =$ fla $c_3 = \frac{f'''\ \alpha}{6}$, then at least the coefficient of e_k^4 disappears. However, we do not know α ,and consequently, $f'\ \alpha$, $f''\ \alpha$ and $f'''\ \alpha$ cannot be data comuted. On the other hand, we can approximate α using available data design of methods with memory consists on the calculation of the parameters $\gamma = \gamma_k$, $p = p_k$ and $\beta = \beta_k$as the iteration proceeds by the formulas $\gamma_k = \frac{-1}{f'\ \alpha}$, $p_k = -c_2 = -\frac{f''\ \alpha}{2f'\ \alpha}$ and $\beta_k =$ fla $c_3 = \frac{f'''\ \alpha}{6}$, $for\ k = 1,2, \ldots\ \ where\ \gamma_k, c_2$ and c_3 are approximations toγ_k, c_2 and c_3, respectively. To this end, the following approximates are applied

$$\gamma_k = \frac{-1}{N'_3(x_k)} \approx \frac{-1}{f'\ \alpha}, p_k = -\frac{N''_4\ w_k}{2N'_4\ w_k} \text{ and } \beta_k = \frac{N'''_5\ y_k}{6}\ , k = 1,2, \ldots. \quad (3.1)$$

where $N_3\ x_k = N_3\ t; x_k, x_{k-1}, y_{k-1}, w_{k-1}$, $N_4\ w_k = N_4\ t; w_k, x_k, x_{k-1}, y_{k-1}, w_{k-1}$, $N_5(y_k) = N_5(t; y_k, w_k, x_k, x_{k-1}, y_{k-1}, w_{k-1})$,

are Newton's interpolating polynomials of third ,fourth and fivth degree, set through four,five and six best available approximations (nodes) $x_k, x_{k-1}, y_{k-1}, w_{k-1}$, $w_k, x_k, x_{k-1}, y_{k-1}, w_{k-1}$ and $y_k, w_k, x_k, x_{k-1}, y_{k-1}, w_{k-1}$, respectively. It should be noted that if one uses lower Newton's interpolation, lower accelerators are obtained. Replacing the fixed parameters γ , p and β in the iterative formula (2.1) by varying γ_k, p_k and β_k calculated by (3.1), we propose the following new method with memory, denoted by NM7,

$$x_0, \gamma_0, p_0, \beta_0\ are\ given, then\ w_0 = x_0 + \gamma_0 f\ x_0\ ,$$

$$\gamma_k = -\frac{1}{N'_3\ x_k}\ , p_k = -\frac{N''_4\ w_k}{N'_4\ w_k}\ , \beta_k = -\frac{N'''_5\ y_k}{6},$$

$$y_k = x_k - \frac{f\ x_k}{f\ x_k, y_k\ + p_k f\ w_k}\ , w_k = x_k + \gamma_k f\ x_k\ ,$$

$$x_{k+1} = y_k - \frac{f\ y_k}{f\ x_k, y_k\ + f\ y_k, w_k\ - f\ x_k, w_k\ + \beta_k\ y_k - x_k\ \ y_k - w_k} \quad (3.2)$$

Here, we concerns the second question regarding convergence order of the method with memory (3.2). We need the next technical result (see[4]).

Lemma 3.1 If $\gamma_k = -\frac{1}{N'_3\ x_k}$, $p_k = -\frac{N''_4\ w_k}{N'_4\ w_k}$, $\beta_k = -\frac{N'''_5\ y_k}{6}$, k = 1,2, ...

then the estimates $(1+\gamma_k fla) \sim C_1 e_{k-1} e_{k-1,w} e_{k-1,y}, p + c_k \sim C_2 e_{k-1} e_{k-1,w} e_{k-1,y},$

$$\beta_k + flac_2\ p + c_2\ - flac_3 \sim C_3 e_{k-1} e_{k-1,w} e_{k-1,y} \quad (3.3)$$

hold, where $C_1, C_2\ and\ C_3$ are some asymptotic constants. The following result determines the convergence order of the two-point iterative method with memory (3.2).

Theorem 3.2 If an initial estimation x_0 is close enough to a simple root α of $f\ x\ = 0$ and $\gamma_0, p_0\ and\ \beta_0$ must be uniformly bounded above, being f a real sufficiently differentiable function, then the R-order of convergence of the two-point method with memory (3.2) is arbitrary close to 7.53.

Theorem 3.3 If an initial estimation x_0 is close enough to a simple root α of $f\ x\ = 0$ and $\gamma_0, p_0\ and\ \beta_0$ must be uniformly bounded above, being f a real sufficiently differentiable function, then the R-order of convergence of the two-point method adaptive with memory (3.2) is arbitrary close to 8 (NM8).

4. Numerical Examples and Conclusion

The errors $|x_k - \alpha|$ of approximations to the sought zeros, produced by the different methods at the first three iterations, are given in Tables 1, 2 where m(−n) stands for $m \times 10^{-n}$. These tables also include, for each test function, the initial estimation values and the last value of the computational order of convergence coc [9] computed by the expression

(if it is stable) $$coc = \frac{\mathrm{Log}(\frac{f(x_k)}{f(x_{k-1})})}{\mathrm{Log}(\frac{f(x_{k-1})}{f(x_{k-2})})} \ . \quad (4.1)$$

The software Mathematica 9, with 2000 arbitrary precision arithmetics, has been used in our computations.Several iterative methods with and without memery, for comparing with our Derivative-free Zheng et al two-step order 4 proposed methods, have been chosen as comes next (ZM)[7]. $y_k = x_k - \frac{f\ x_k}{f\ x_k, y_k}$, $w_k = x_k + \gamma f\ x_k$,

$$x_{k+1} = y_k - \frac{f\ y_k}{f\ x_k, y_k\ + f\ y_k, x_k, w_k\ \ y_k - x_k} \quad (4.2)$$

Derivative-free Petkovic et al two-step with memory with order $2 + \sqrt{6} \cong 4.44$ (PM)[8].

$$y_k = x_k - \frac{f\ x_k}{\emptyset_k}\ , w_k = x_k - \gamma f\ x_k\ \ , u_k = \frac{f\ y_k}{f\ x_k}, v_k = \frac{f\ y_k}{f\ w_k},$$

$$h\ u_k, v_k\ = \frac{1-u_k}{1+v_k}\ , \emptyset_k = \frac{f\ x_k\ - f\ w_k}{x_k - w_k}\ x_{k+1} = y_k - h\ u_k, v_k\ * \frac{f\ y_k}{\emptyset_k} \qquad (4.3)$$

Derivative-free Lotfi et al two-step with memory order 6 (LM)[10].

$$y_k = x_k - \frac{f\ x_k}{f\ x_k, y_k}\ , w_k = x_k + \gamma f\ x_k\ , x_{k+1} = y_k - \frac{f\ y_k}{p'_2\ y_k} \qquad (4.4)$$

$$p'_2\ y_k\ = \frac{2y_k - y_k - x_k}{x_k - w_k\ \ x_k - y_k} f\ x_k\ + \frac{2y_k - x_k - y_k}{w_k - x_k\ \ w_k - y_k} f\ w_k\ + \frac{2y_k - w_k - x_k}{y_k - w_k\ \ y_k - x_k} f\ y_k\ f\ w_k$$

Derivative-free Cordero et al two-step with memory order 7 (CM)[11].

$$\gamma_k = -\frac{1}{N'_3\ x_k}\ , p_k = -\frac{N''_4\ w_k}{N'_4\ w_k}\ ,$$

$$y_k = x_k - \frac{f\ x_k}{f\ x_k, y_k\ + p_k f\ w_k}\ , w_k = x_k + \gamma_k f\ x_k\ ,$$

$$x_{k+1} = y_k - \frac{f\ y_k}{f\ x_k, y_k\ + f\ y_k, w_k\ - f\ x_k, w_k\ + \beta\ y_k - x_k\ \ y_k - w_k} \qquad 4.5$$

Table 1 $\mathrm{f}_1\ \mathrm{t}\ = 1 + \frac{1}{\mathrm{t}^4} - \frac{1}{\mathrm{t}} - \mathrm{t}^2, \alpha = 1, \mathrm{x}_0 = 1.4, \mathrm{p}_0 = 0.1, \beta_0 = 0.01, \gamma_0 = 0.1$

In Tables 1–2 we have examined some methods with different kinds of convergence order. It is observed that these methods support their theoretical aspects.The last columns of Tables show computational efficiency index defined by IE = $\mathrm{COC}^{1/3}$. It is asymptotically 2. In other words, our three parametric with memory method (3.3), shows a behavior as optimal n-point without memory methods.Therefore, we can conclude the following:
We have developed a new three parametric with memory method which has efficiency index 2. However, such task is only of theoretical importance, since developing methods with efficiency index more than 2 is impossible.Moreover,our developed method (3.3) does not need any derivatives and can be used even for non-smooth functions. Studying basins of attraction of the methods in this work may be considered for future research.

Abstract

The problem of high-intensive laser pulse influence on semiconductor with nonlinear absorption is considered. The conservative finite-difference scheme efficiency for complicated nonlinear processes computation is proposed. Computer simulation results are presented.

Key words: conservative finite-difference scheme, optical bistability, femtosecond pulse

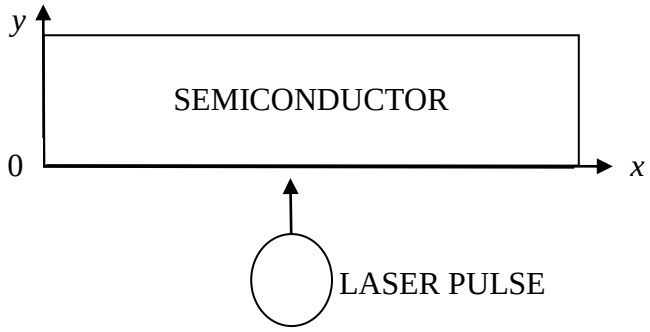
1. Introduction

We consider a 2D problem of femtosecond laser pulse interaction with semiconductor under the condition of field optical bistability (OB) occurrence. This is very promising phenomenon for the creation and developing of all-optical data processing. In the case of OB existence, the hysteresis dependence of semiconductor characteristics on laser pulse intensity and also kink structure of a high absorption appears. Existence of this phenomena is based on the laser radiation non-linear absorption of a semiconductor.

The laser pulse interaction with a semiconductor is described by the set of nonlinear partial differential equations. The laser pulse propagation in a semiconductor is described by a nonlinear Schrödinger equation with respect to the envelope (complex amplitude) of wave pocket. We developed a conservative finite-difference scheme (FDS) for this problem. It is a nonlinear one, so to realize it we proposed an original two-step iteration process. The FDS is also conservative one on the each of iterations. Computer simulation results confirmed

that the FDS possesses an asymptotic stability property. This property is very important because we should provide calculation during long time interval. One of the features of proposed approach for the nonlinear FDS realization is an opportunity of its generalizing for multidimensional problem.

2. Problem Statement and FDS



The process of laser pulse interaction with a semiconductor is described by the following set of 2D dimensionless differential equations concerning semiconductor characteristics - free electron concenration *n(x,y,t)*, ionized donors concentration *N(x,y,t)*, electric field potential $\varphi(x,y,t)$ [1, 2] and complex amplitude *A(x,y,t)*:

$$\frac{\partial^2\varphi}{\partial x^2}+\frac{\partial^2\varphi}{\partial y^2}=\gamma(n-N),\ \frac{\partial N}{\partial t}=G(n,N,\varphi)-R(n,N),\ 0<x<L_x,\ 0<y<L_y,\ t>0.$$

$$\frac{\partial n}{\partial t}=D_x\frac{\partial}{\partial x}\left(\frac{\partial n}{\partial x}-\mu_x n\frac{\partial\varphi}{\partial x}\right)+D_y\frac{\partial}{\partial y}\left(\frac{\partial n}{\partial y}-\mu_y n\frac{\partial\varphi}{\partial y}\right)++G(n,N,\varphi)-R(n,N),$$

$$\frac{\partial A}{\partial t}+iD_{Ax}\frac{\partial^2 A}{\partial x^2}+iD_{Ay}\frac{\partial^2 A}{\partial y^2}+\frac{\beta_A\delta_0}{2}\delta(n,N,\varphi)A=0\,,0<x<L_x,\ -L_y<y<L_y,\ t>0.$$

Boundary conditions (BC) and initial condition are written below:

$$\left(\frac{\partial n}{\partial x}-\mu_x n\frac{\partial\varphi}{\partial x}\right)\Bigg|_{x=0,L_x}=\left(\frac{\partial n}{\partial y}-\mu_y n\frac{\partial\varphi}{\partial y}\right)\Bigg|_{y=0,L_y}=0,\ \frac{\partial\varphi}{\partial x}\Bigg|_{x=0,L_x}=\frac{\partial\varphi}{\partial y}\Bigg|_{y=0,L_y}=0.$$

$$A\big|_{x=0,L_x}=A\big|_{y=0,L_y}=0,\ A\big|_{t=0}=e^{-\frac{(x-L_{xc})^2}{a^2}-(y-L_{yc})^{10}-2i\pi\chi(y-L_{yc})}.$$

This homogenous BC correspond to both the electric current absence through semiconductor faces and external electric field absence. Below the following functions are introduced: generation *G* and recombination *R* of free electrons

$$G(n,N,\varphi,A)=q_0|A|^2\,\delta(n,N,\varphi),\ R(n,N)=\frac{nN-n_0^2}{\tau_R}.$$

Absorption coefficient $\delta(n,N,\varphi)$ could be approximated by different ways, in our paper we consider its folowing approximation:

$$\delta_n(n,N,\varphi)=(1-N)e^{-\psi(1-\xi n)}.$$

It should be stressed, that we take into account the diffraction phenomena to describe the laser pulse reflection from the inhomogeneities induced by laser radiation in semiconductor. This is a very important feature of such problem statement and it has not been described in literature earlier.

The law of charge preservation takes place for this problem, therefore the FDS conservatism consists in validity of this invariant difference analog.

To solve the differential initial-boundary problem numerically we approximate it by the set of finite-difference equations. We use uniform space and time grids in rectangular domain and standard notations of the first and the second difference derivatives for this purpose. As a result, we propose the following FDS in the inner nodes of the grids:

$$\varphi_{\bar{x}x}+\varphi_{\bar{y}y}=\gamma(\hat{n}-\hat{N}),\quad \frac{\hat{N}-N}{\tau}=0.5\left(\hat{G}+G\right)-0.5\left(\hat{R}+R\right),$$

$$\frac{\hat{n}-n}{\tau}=0.5D_x\left(\hat{n}_{\bar{x}x}+n_{\bar{x}x}\right)+0.5D_y\left(\hat{n}_{\bar{y}y}+n_{\bar{y}y}\right)+0.5\left(\hat{G}+G\right)-0.5\left(\hat{R}+R\right)-$$

$$-0.5\frac{D_x\mu_x}{h_x}\left(\hat{n}_{k+0.5}\hat{\varphi}_x-\hat{n}_{k-0.5}\hat{\varphi}_{\bar{x}}+n_{k+0.5}\varphi_x-n_{k-0.5}\varphi_{\bar{x}}\right)-$$

$$-0.5\frac{D_y\mu_y}{h_y}\left(\hat{n}_{j+0.5}\hat{\varphi}_y-\hat{n}_{j-0.5}\hat{\varphi}_{\bar{y}}+n_{j+0.5}\varphi_y-n_{j-0.5}\varphi_{\bar{y}}\right),$$

$$\frac{\hat{A}-A}{\tau}+iD_{A_x}\overset{0.5}{A}_{\bar{x}x}+iD_{A_y}\overset{0.5}{A}_{\bar{y}y}+\frac{\beta_A\delta_0}{2}\overset{0.5}{\delta}\overset{0.5}{A}=0.$$

This FDS has the second order of approximation on time and space coordinates in inner grid nodes. BC for electric field potential and free electron concentration are approximated with the first order because of the scheme conservative property requirement.

To solve the obtained system of 2D nonlinear difference equations we use two-stage iteration process [3]. We constructed it in such a way, that the FDS becomes a conservative one on each of iterations. It is an important feature of our approach. Such approach allows to avoid disadvantages which arise from split-step method using, because this method accumulates computing mistakes at calculating non-stationary problem on a big time interval and, therefore, asymptotic stability property violation takes place.

Abstract

The symmetric and symplectic conditions and exponential fitting conditions for modified Runge-Kutta methods are presented. Two new exponentially fitted symmetric and symplectic diagonally implicit Runge-Kutta (EFSSDIRK) methods of respective second order and fourth order are derived. Implementation on the Kepler problem shows the high effectiveness and competence of the new methods compared to three four order DIRK methods in the recent literature.

Keywords: Exponential fitting, symmetry, symplecticity, Hamiltonian problem
MSC 2000: 65L04, 65L05, 65L06

1 Introduction

In this paper, we focus on the effective integration of the initial value problem of the first order differential system in the form

$$\dot{y} = f(t, y), \quad y(x_0) = y_0, \tag{1}$$

which arise in sciences such as celestial mechanics, astrophysics, chemistry biology and engineering. In many applications, the problem (1) takes the form of a Hamiltonian system,

that is the function $f(t,y) = J^{-1}\nabla H(p,q)$ with $J = \begin{pmatrix} 0 & I_d \\ -I_d & 0 \end{pmatrix}$, where $H = H(p,q) = H(p_1,\ldots,p_d,q_1,\ldots,q_d)$ is the *Hamiltonian energy*. A special class of numerical integrators, called *symplectic integrators*, have been proved to be very effective for Hamiltonian systems due to the preservation of the symplectic structure of the solution.

2 Exponentially fitted symmetric and symplectic diagonally implicit Runge-Kutta methods

Suppose the solution to the problem (1) is oscillatory with frequency ω, we consider the modified implicitly diagonal Runge-Kutta methods of the form

$$\begin{aligned} Y_i &= \eta_i y_n + h\sum_{j=1}^{i} a_{ij} f(x_n + c_j h, Y_j), \quad i = 1,\ldots,s, \\ y_{n+1} &= y_n + h\sum_{i=1}^{s} b_i f(x_n + c_i h, Y_i), \end{aligned} \tag{2}$$

where h is the stepsize, η_i, b_i, a_{ij}, c_i, $1 \le j \le i \le s$ are assumed to be even functions of $z = \mathrm{i}\omega h$ ($\mathrm{i}^2 = -1$). It is usually assumed that $\lim_{z\to 0}\eta_i(z) = 1$ so that as $z \to 0$, the scheme (2) reduces to a traditional Runge-Kutta method.

According the Tsitouras et al. [6], the local truncation error of the modified RK method (2) can be expressed as

$$LTE = \sum_{\tau\in\mathcal{T}} \frac{h^{\rho(\tau)}}{\rho(\tau)!}(\gamma(\tau)b(z)^T\Phi(\tau) - 1)\alpha(\tau)\mathcal{F}(\tau)(y_0) + \sum_{\tau\in\widetilde{\mathcal{T}}} \frac{h^{\rho(\tau)}}{\rho(\tau)!}(\gamma(\tau)b(z)^T\widetilde{\Phi}(\tau) - 1)\alpha(\tau)\widetilde{\mathcal{F}}(\tau)(y_0), \tag{3}$$

where $\mathcal{T}$ ($\widetilde{\mathcal{T}}$) is the set of (modified) rooted trees, $\mathcal{F}(\tau)(y_0)$ ($\widetilde{\mathcal{F}}(\tau)(y_0)$) is the elementary differential of f associated to $\tau \in \mathcal{T}$ ($\widetilde{\mathcal{T}}$) at y_0, $\gamma(\tau)$ is the density of the tree τ, $\alpha(\tau)$ is the number of monotonic labellings of τ and $\Phi(\tau)$ ($\widetilde{\Phi}(\tau)$) is the elementary weight coefficient which depends on $A(z)$ and $\eta(z)$.

The modified Runge-Kutta method of the form (2) has order p if for any sufficiently smooth problem (1), under the assumption that $y(x_0) = y_0$, the local truncation error of the solution satisfies

$$LTE = y(x_0 + h) - y_0 = \mathcal{O}(h^{p+1}) \quad \text{as} \quad h \to 0. \tag{4}$$

 ISBN: 978-84-608-6082-2

For example, the conditions for the method (2) to be of order four are listed as follows:

$$\begin{array}{lll}
\eta_i = 1 + \mathcal{O}(z^2), & \sum\limits_i b_i = 1 + \mathcal{O}(z^4), & \sum\limits_i b_i\eta_i = 1 + \mathcal{O}(z^4), \\
\sum\limits_{i,j} b_i a_{ij}\eta_j = \frac{1}{2} + \mathcal{O}(z^3), & \sum\limits_{i,j} b_i\eta_i a_{ij} = \frac{1}{2} + \mathcal{O}(z^3), & \sum\limits_{i,j} b_i a_{ij} = \frac{1}{2} + \mathcal{O}(z^3), \\
\sum\limits_{i,j,k} b_i a_{ij} a_{jk} = \frac{1}{6} + \mathcal{O}(z^2), & \sum\limits_{i,j} b_i c_i^2 = \frac{1}{3} + \mathcal{O}(z^2), & \sum\limits_{i,j} b_i c_i^3 = \frac{1}{4} + \mathcal{O}(z), \\
\sum\limits_{i,j} b_i a_{ij} c_j^2 = \frac{1}{12} + \mathcal{O}(z), & \sum\limits_{i,j,k} b_i c_i a_{ij} a_{jk} = \frac{1}{8} + \mathcal{O}(z), & \sum\limits_{i,j,k,l} b_i a_{ij} a_{jk} a_{kl} = \frac{1}{24} + \mathcal{O}(z).
\end{array} \tag{5}$$

The method (2) is symmetric if

$$\begin{array}{l}
c_i = 1 - c_{s+1-i}, \quad \eta_i = \eta_{s+1-i}, \quad b_i(z) = b_{s+1-i}(z), \quad i = 1, \ldots, s, \\
a_{ij} = \eta_i(z) b_j(z), \quad 1 \le j < i \le s, \\
a_{ii} + a_{s+1-i,s+1-i} = \eta_i(z) b_i(z), \quad i = 1, \ldots, s.
\end{array} \tag{6}$$

The method (2) is symplectic if its coefficients satisfy the following conditions

$$a_{ij} = \eta_i b_j \quad \text{for} \quad 1 \le j < i \le s, \quad a_{ii} = \frac{1}{2}\eta_i b_i \quad \text{for} \quad 1 \le i \le s. \qquad i, j = 1, \ldots, s. \tag{7}$$

The method (2) is exponentially fitted if its internal stages and the update are exact for the functions $\{\exp(\pm\omega x)\}$ leading to:

$$\begin{array}{l}
\sum\limits_{j=1}^{i} a_{ij} \sinh(c_i z) = \frac{\cos(c_i z) - \eta_i}{z}, \quad \sum\limits_{j=1}^{i} a_{ij} \cosh(c_i z) = \frac{\sin(c_i(z) z)}{z}, \quad i = 1, \ldots, s, \\
\sum\limits_{i=1}^{s} b_i \sinh(c_i z) = \frac{\cos(z) - 1}{z}, \quad \sum\limits_{i=1}^{s} b_i \cosh(c_i z) = \frac{\sin(z)}{z}.
\end{array} \tag{8}$$

A 2-stage symmetric and symplectic exponentially fitted DIRK method of order two is given by

$$\begin{array}{l}
c_1 = 1/4, \quad c_2 = 3/4, \quad \eta_1 = \frac{1}{\cosh(c_1 z)}, \quad \eta_2 = \eta_1, \quad a_{11} = \frac{\tanh(c_1 z)}{z}, \quad a_{21} = 2a_{11}, \\
a_{22} = \frac{\sin(c_2 z) - 2\sinh(c_1 z)}{z\cosh(c_2 z)}, \quad b_1 = \frac{\cosh((c_2 - 1)z) - \cosh(c_2 z)}{z\sinh((c_1 - c_2)z)}, \quad b_2 = b_1.
\end{array} \tag{9}$$

The method is denoted as EFSSDIRK2.

A 3-stage symmetric and symplectic exponentially fitted DIRK method of order four is

 ISBN: 978-84-608-6082-2

obtained as follows

$$
\begin{aligned}
&c_1 = \left(\tfrac{1}{3} + \tfrac{2^{1/3}}{6} + \tfrac{2^{2/3}}{12}\right) - \tfrac{1}{864}\left(1 + 2^{2/3} + 2^{4/3}\right) z^2 - \tfrac{1}{414720}\left(23 \cdot 2^{1/3} - 22 \cdot 2^{2/3} - 36\right) z^4 + \ldots,\\
&c_2 = 1/2, \quad c_3 = 1 - c_1, \quad \eta_1 = \tfrac{1}{\cosh((1-c_3)z)}, \quad \eta_3 = \eta_1\\
&\eta_2 = \tfrac{4(3c_3^2-3c_3+1) - \cosh\left(\frac{z}{2}(1-2c_3)\right)}{4\left(3c_3^2-3c_3+1\right)\cosh\left(\frac{z}{2}\right) + z\sinh\left(\frac{z}{2}(1-2c_3)\right) - \cosh(z-c_3 z)},\\
&a_{11} = a_{33} = \tfrac{1}{2}\eta_3 b_3, \quad a_{21} = \eta_2 b_3, \quad a_{22} = \tfrac{1}{2}\eta_2 b_2, \quad a_{31} = 2a_{11}, \quad a_{32} = \eta_3 b_2.\\
&b_1 = \tfrac{-2z\sinh\left(\frac{z}{2}(1-2c_3)\right) + \cosh((1-c_3)z) - \cosh(3z)}{z\left(8c_3^3\sinh\left(\left(c_3-\frac{1}{2}\right)z\right) + 2\sinh\left(\frac{z}{2}(1-2c_3)\right)\left(\cosh\left(\frac{z}{2}(1-2c_3)\right) + 4(c_3-1)^3\right)\right)},\\
&b_2 = \tfrac{4\sinh\left(\frac{z}{2}(1-2c_3)\right)\left(z\cosh\left(\frac{z}{2}(1-2c_3)\right) - 4\left(3c_3^2-3c_3+1\right)\sinh\left(\frac{z}{2}\right)\right)}{z\left(8c_3^3\sinh\left(\left(c_3-\frac{1}{2}\right)z\right) + 2\sinh\left(\frac{z}{2}(1-2c_3)\right)\left(\cosh\left(\frac{z}{2}(1-2c_3)\right) + 4(c_3-1)^3\right)\right)},\\
&b_3(z) = b_1(z).
\end{aligned}
\tag{10}
$$

The method is denoted as EFSSDIRK4. As $z \to 0$, the method reduces to a classical four-stage DIRK proposed by Sans-Serna and Abia [5] and Feng and Qin [3], which is denoted as SSDIRK4.

3 Numerical experiments on the Kepler problem

To examine the numerical effectiveness of the newly constructed SSEFDIRK4, we apply it to the Kepler problem

$$
p_1' = -\tfrac{q_1}{\sqrt{(q_1^2+q_2^2)^3}}, \quad p_2' = -\tfrac{q_2}{\sqrt{(q_1^2+q_2^2)^3}}, \quad q_1' = p_1, \quad q_2' = p_2, . \tag{11}
$$

The Hamiltonian of this problem is given by $H(p_1, p_2, q_1, q_2) = \frac{1}{2}(p_1^2 + p_2^2) - \left(q_1^2 + q_2^2\right)^{-1/2}$. For initial values $q_1(0) = 1,\ p_1(0) = 0,\ q_2(0) = 0,\ p_2(0) = 1$, the exact solution of (11) is $q_1(x) = \cos(x)$, $q_2(x) = \sin(x)$.

Four highly efficient DIRK methods of order four are selected from the literature for comparison listed as follows: DIRK4A (Alexander [1]), DIRK4C (Cash [2]), SSDIRK4SA (Sanz-Serna and Abia [5]) and TFSDIRK4K (Kalogiratou [4]).

The effectiveness of the previous methods will be compared in terms of accuracy and efficiency. We test the accuracy of the methods in the terms (P, Q), where P represents the decimal logarithm of the maximum global error $\log_{10}(\text{MGE})$ and Q represents the computational effort required by each method which is measured by the decimal logarithm of the number of function evaluations$\log_{10}(\text{NFE})$. We also check the efficiency in terms of $R = \text{MGE} \times \text{NFE}$.

We take the fitting frequency as $\omega = 1$ and integrate the problem on the interval $[0, 100\pi]$ with different stepsizes $h = \frac{\pi}{16}, \frac{\pi}{32}, \frac{\pi}{64}, \frac{\pi}{128}$. The numerical results are presented in Table 1 and Table 2 .

 ISBN: 978-84-608-6082-2

Table 1: Maximum global error vs number of function evaluations

(P,Q)	$\frac{\pi}{16}$	$\frac{\pi}{32}$	$\frac{\pi}{64}$	$\frac{\pi}{128}$
EFSSDIRK2	$(-11.84, 4.57)$	$(-11.41, 4.74)$	$(-11.68, 4.95)$	$(-11.66, 5.19)$
EFSSDIRK4	$(-8.00, 4.96)$	$(-10.62, 5.09)$	$(-11.41, 5.25)$	$(-11.77, 5.45)$
DIRK4N	$(0.34, 4.85)$	$(0.22, 4.97)$	$(-1.24, 5.11)$	$(-2.76, 5.25)$
SSDIRK4SA	$(-0.35, 4.78)$	$(-1.61, 4.90)$	$(-2.83, 5.06)$	$(-4.03, 5.22)$
TFSDIRK4K	$(-6.42, 4.76)$	$(-5.67, 4.87)$	$(-6.46, 5.04)$	$(-6.08, 5.19)$

Table 2: Comparison of computational efficiency

R	$\frac{\pi}{16}$	$\frac{\pi}{32}$	$\frac{\pi}{64}$	$\frac{\pi}{128}$
EFSSDIRK2	$5.26E-8$	$2.12E-7$	$1.87E-7$	$3.33E-7$
EFSSDIRK4	$9.04E-4$	$2.96E-6$	$6.99E-7$	$4.82E-7$
DIRK4N	$1.51E-0$	$1.55E-0$	$7.37E-2$	$3.15E-3$
SSDIRK4SA	$2.69E-0$	$1.97E-1$	$1.72E-2$	$1.55E-3$
TFSDIRK4K	$2.17E-2$	$1.56E-1$	$3.75E-2$	$1.26E-1$

From Tables 1 and 1 we can see that the new methods EFSSDIRK2 and EFSSDIRK3s4 outperform the other methods we choose for comparison when applied to the Kepler problem. Among all the five methods, the second order EFSSDIRK2 is the most accurate and most efficient although the other methods are fourth order.

Multidimensional adapted RKN methods for multi-frequency oscillatory systems

Yonglei Fang[1]

[1] *School of Mathematics and Statistics, Zaozhuang University*

emails: ylfangmath@163.com

Abstract

Multidimensional adapted Runge-Kutta-Nyström (MARKN) methods with optimized phase properties for multi-frequency oscillatory systems are obtained in this paper. The new methods are of order five. We analyze the stability and the phase properties of the higher order methods. Numerical results are carried out to show the efficiency of our new methods for the numerical integration of the multi-frequency oscillatory systems.

Key words: Multidimensional ARKN pair, Multi-frequency oscillatory system, Variable step-size, Phase-lag.
MSC 2000: 65L05

1 Introduction

In this paper we are concerned with the numerical integration of the system of the form

$$\begin{cases} y''(t) + My(t) = f(y(t)), \quad t \in [t_0, t_{\text{end}}], \\ y(t_0) = y_0, \quad y'(t_0) = y_0', \end{cases} \tag{1}$$

in which $M \in \mathbb{R}^{m\times m}$ is a symmetric positive semi-definite matrix (stiffness matrix) and $f : \mathbb{R}^m \to \mathbb{R}^m$, $y_0 \in \mathbb{R}^m, y_0' \in \mathbb{R}^m$. We will consider the construction of multidimensional ARKN methods with optimized phase properties for the numerical integration of multi-frequency oscillatory systems.

 ISBN: 978-84-617-8694-7

2 Multidimensional ARKN methods

For any matrix $M \in \mathbb{R}^{m\times m}$, we introduce the following matrix-valued functions [1]:

$$\phi_j(M) := \sum_{k=0}^{\infty} \frac{(-1)^k M^k}{(2k+j)!}, \quad j = 0, 1, 2, \ldots. \tag{2}$$

For the numerical integration of problem (1), a multidimensional ARKN method has the form

$$\begin{cases} Y_i = y_n + hc_i y_n' + h^2 \sum\limits_{j=1}^{s} \bar{a}_{ij}\big(f(Y_j) - MY_j\big), \qquad i = 1, \cdots, s, \\ y_{n+1} = \phi_0(V) y_n + h\phi_1(V) y_n' + h^2 \sum\limits_{i=1}^{s} \bar{b}_i(V) f(Y_i), \\ y_{n+1}' = \phi_0(V) y_n' - hM\phi_1(V) y_n + h \sum\limits_{i=1}^{s} b_i(V) f(Y_i), \end{cases} \tag{3}$$

in which the weight functions $b_i(V) \in R^{m\times m}$ and $\bar{b}_i(V) \in R^{m\times m}, i = 1, \cdots, s$ in the final stages are functions of V with $V = h^2M$ and the scheme (3) can be expressed in the Butcher tableau as

$$\begin{array}{c|c} c & \bar{A} \\ \hline & \bar{b}^T(V) \\ \hline & \bar{b}^T(V) \end{array} = \begin{array}{c|ccc} c_1 & \bar{a}_{11} & \ldots & \bar{a}_{1s} \\ \vdots & \vdots & \ddots & \vdots \\ c_s & \bar{a}_{s1} & \cdots & \bar{a}_{ss} \\ \hline & \bar{b}_1(V) & \cdots & \bar{b}_s(V) \\ \hline & b_1(V) & \ldots & b_s(V) \end{array}$$

or equivalently by the quadruple $(c, \bar{A}, \bar{b}(V), b(V))$. The order conditions for the multidimensional ARKN method are given by Wu et. al in [2].

The stability of ARKN methods can be analyzed by the test equation of the form (see [3])

$$y''(t) + \omega^2 y(t) = -\epsilon y(t), \tag{4}$$

with $\omega^2 + \epsilon > 0$. Applying the ARKN methods to the test problem (4) yields

$$\begin{pmatrix} y_{n+1} \\ hy_{n+1}' \end{pmatrix} = M(V, z) \begin{pmatrix} y_n \\ hy_n' \end{pmatrix},$$

where

$$M(V, z) = \begin{pmatrix} \phi_0(V) - z\bar{b}^T(V)N^{-1}e & \phi_1(v) - z\bar{b}^T(V)N^{-1}c \\ -V\phi_1(V) - zb^T(V)N^{-1}e & \phi_0(V) - zb^T(V)N^{-1}c \end{pmatrix},$$

with $N = I + (V + z)\bar{A}$, $e = (1, 1, \cdots, 1)^T$ and I the identity matrix.

For the numerical integration of oscillatory problems, it is very important to consider the phase properties of ARKN methods. So, we refer to the following definition.

 ISBN: 978-84-617-8694-7

Definition 2.1 *The quantities [1, 3, 4, 5]*

$$\phi(H) = H - \arccos\left(\frac{\mathrm{tr(M)}}{2\sqrt{\det(M)}}\right), \quad d(H) = 1 - \sqrt{\det(M)},$$

are called the dispersion error and the dissipation error, respectively, where $H = \sqrt{V+z}$ *. Therefore, an ARKN method is said to be dispersive of order* q *and dissipative of order* p *if*

$$\phi(H) = \mathcal{O}(H^{q+1}), \quad d(H) = \mathcal{O}(H^{p+1}).$$

If $\phi(H) = 0$ *and* $d(H) = 0$*, then the method is said to be zero dispersive and zero dissipative.*

3 Construction of new multidimensional ARKN methods

We consider the fourth-stage explicit multidimensional ARKN methods which are expressed by the following Butcher-tableau:

$$\begin{array}{c|c} c & \bar{A} \\ \hline & \bar{b}^T(V) \\ \hline & b^T(V) \end{array} = \begin{array}{c|cccc} 0 & 0 & 0 & 0 & 0 \\ c_2 & \bar{a}_{21} & 0 & 0 & 0 \\ c_3 & \bar{a}_{31} & \bar{a}_{31} & 0 & 0 \\ c_4 & \bar{a}_{41} & \bar{a}_{42} & \bar{a}_{43} & 0 \\ \hline & \bar{b}_1(V) & \bar{b}_2(V) & \bar{b}_3(V) & \bar{b}_4(V) \\ \hline & b_1(V) & b_2(V) & b_s(V) & b_4(V) \end{array}$$

With the choice of $\bar{A}e = \frac{c^2}{2}$ and we solve the order condition equations up to order five and obtain

$$\bar{b}_1(V) = \bar{b}_1(c_2, c_3, c_4, V), \bar{b}_2(V) = \bar{b}_2(c_2, c_3, c_4, V), \bar{b}_3(V) = \bar{b}_2(c_2, c_3, c_4, V),$$

$$\bar{b}_4(V) = \bar{b}_2(c_2, c_3, c_4, V), b_1(V) = b_1(c_2, c_3, c_4, V), b_2(V) = b_2(c_2, c_3, c_4, V),$$

$$b_3(V) = b_3(c_2, c_3, c_4, V), b_4(V) = b_4(c_2, c_3, c_4, V), \bar{a}_{31} = \frac{c_3^2}{2} - a_{32}, \ \bar{a}_{41} = \frac{c_4^2}{2} - a_{42} - a_{43},$$

$$\bar{a}_{43} = (c_4(5c_2 - 2)(c_2 - c_4)(c_3 - c_4))/(10c_3(c_3(4c_3 - 3) + c_2^2(6c_3 - 4) + c_2(3 - 6c_3^2))),$$

$$\bar{a}_{32} = (c_2 - c_3)c_3(5c_4 - 4)/(10c_2(3 - 4c_4 + c_2(6c_4 - 4))),$$

$$\bar{a}_{42} = (-2a_{43}c_3^2(c_3(4c_3 - 3) + c_2^2(6c_3 - 4) + c_2(3 - 6c_3)) + (c_2 - c_4)c_4((c_2 - c_3)c_3(c_3 - c_4)$$

$$+2a_{32}c_2(3 - 4c_2 - 4c_4 + 6c_2c_4)))/(2c_2(c_2 - c_3)c_3(3 - 4c_3 + c_2(6c_3 - 4))),$$

$$c_3 = (12 - 15c_2 - 15c_4 + 20c_2c_4)/(15 - 20c_2 - 20c_4 + 30c_2c_4).$$

 ISBN: 978-84-617-8694-7

As an example, choosing $c_2 = \frac{3}{10}$, we give the dispersion and the dissipation of the methods

$$\phi(H) = -\frac{\epsilon\big(45(164 - 433c_4 + 280c_4^2)\epsilon + (4752 - 15643c_4 + 11830c_4^2)\omega^2\big)H^7}{2016000((11c_4 - 9)\big(\epsilon + \omega^2)^2\big)} + \mathcal{O}(H^9),$$

$$d(H) = -\frac{\epsilon\big((96 - 254c_4 + 165c_4^2)\epsilon + (69 - 221c_4 + 165c_4^2)\omega^2\big)H^6}{14400\big((11c_4 - 9)(\epsilon + \omega^2)^2\big)} + \mathcal{O}(H^8).$$

Assuming that $\omega \gg \epsilon$, we select the free parameter c_4 so that the dispersion or the dissipation are optimized.

Case(a): Firstly, we choose the free parameter so that the error constant of the dispersion is minimal in the sense that this constant is of order $\mathcal{O}(\epsilon)$, obtaining $c_4 = (15643 + \sqrt{19838809})/23660$. We denote this method as ARKN4S5I.

Case(b): Secondly, we choose the free parameter so that the error constant of the dissipation is minimal and we obtain $c_4 = (221 + \sqrt{3301})/330$. We denote this method as ARKN4S5II.

4 Numerical experiments

In this section, we will compare the numerical performance of the new methods with some existing codes proposed in the scientific literature. The criterion used in the numerical comparisons is the decimal logarithm of the maximum global error (LOG10 (ERROR)) versus the computational effort measured by the number of function evaluations (NUMBER OF FUNCTION EVALUATIONS) required by each method. We select two multidimensional multi-frequency oscillatory systems as test problems and the methods for comparison are listed below:

- ARKN3S4F: the three-stage ARKN method of order four with minimal error constant of dispersion error given in [3].
- ARKN3S4W: the three-stage ARKN method of order four with minimal error constant of dissipation error given in [1].
- W1ERKN3s3, W2ERKN3s3: the two three-stage multidimensional ERKN methods derived in [5].
- SSMERKN3S4: the three-stage symplectic and symmetric Multidimensional ERKN given in [6].
- ARKN4S5W: the four-stage multidimensional ARKN method given in [1].

 ISBN: 978-84-617-8694-7

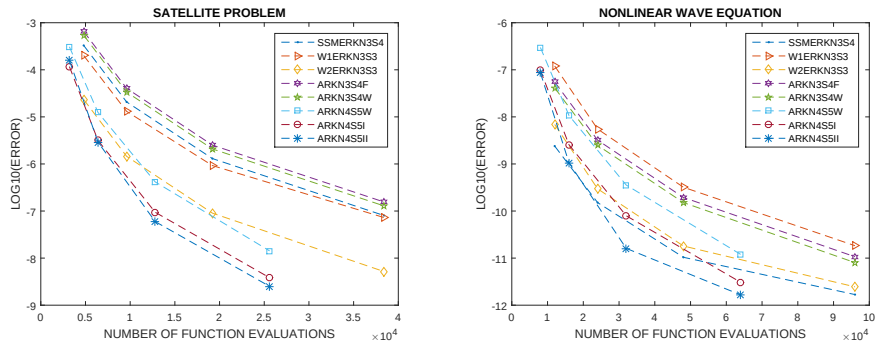

Figure 1: Efficiency curves in Problem 1 and Problem 2

- ARKN4S5I, ARKN4S5II: the two four-stage multidimensional ARKN methods derived in this paper.

Problem 1. We consider the equation governing the motion of an artificial satellite [7]

$$\vec{u}'' + \frac{\hbar}{2}\vec{u} = -\frac{1}{4}\frac{\partial(V|\vec{u}|^2)}{\partial\vec{u}},$$

with $\hbar = \dfrac{K^2}{r_0} - \dfrac{1}{2}|\dot{u}_0|^2 - V_0$, where $\hbar$ is the total energy of the elliptic motion, V is the perturbing potential of the earth. The initial conditions are considered on an elliptic equatorial orbit with $e = 0.1$, $K^2 = 3.98601 \times 10^5$, $r = 6.8 \times 10^3$, $\vartheta = 3.0 \times 10$, $\varrho = 3.844 \times 10^5$, $\lambda = 4.90266 \times 10^3$. The problem is solved on the interval $[0, 100]$ and the numerical results are reported in Fig. 1 (on the left).

Problem 2. Consider the initial-boundary value problem of the nonlinear wave equation

$$\begin{cases} \dfrac{\partial^2 u}{\partial t^2} - \dfrac{\partial^2 u}{\partial x^2} = u^5 - u^3 - \dfrac{1}{2}u, \quad 0 < x < 1, t > 0, \\ u(0,t) = 0, \quad u(1,t) = 0, \quad u(x,0) = \dfrac{x(1-x)}{100}, \quad u_t(x,0) = 0. \end{cases}$$

The method of lines is a technique for solving partial differential equation (PDEs). By using second order symmetric differences, the problem is converted to the initial value problem of an oscillatory system of the form

$$\begin{cases} \ddot{U} + MU = F(U), \\ U(0) = \left(\dfrac{x_1(1-x_1)}{100}, \cdots, \dfrac{x_{N-1}(1-x_{N-1})}{100}\right)^T, \ U'(0) = \mathbf{0}, \end{cases}$$

 ISBN: 978-84-617-8694-7

in which $U(t) = (u_1(t), \cdots, u_{N-1}(t))^T, u_i(t) \approx u(x_i, t), x_i = i\Delta x,\ i = 1, \cdots, N-1, \Delta x = 1/N$,

$$M = \frac{1}{\Delta x^2}\begin{pmatrix} 2 & -1 & & & \\ -1 & 2 & -1 & & \\ & \ddots & \ddots & \ddots & \\ & & -1 & 2 & -1 \\ & & & -1 & 2 \end{pmatrix},$$

$$F(U) = \left(u_1^5 - u_1^3 - \frac{1}{2}u_1, \cdots, u_{N-1}^5 - u_{N-1}^3 - \frac{1}{2}u_{N-1}\right)^T.$$

In this test, we choose $N = 20$. The system is integrated on the interval [0,100] and the numerical results are reported in Fig. 1 (on the right).

Abstract

An adapted explicit four-step method for the numerical integration of perturbed oscillators is obtained by refining the classical method of power series. The local truncation error, phase properties and linear stability of the new method are analyzed. Numerical experiments are reported to show the accuracy and efficiency of the new method when it is compared with some high-quality methods recently proposed in the literature.

Keywords: Variation-of-constant formula; adapted method; perturbed oscillator; efficiency

1 Introduction

We are concerned the numerical integration of perturbed oscillators which are second-order initial value problems of the form

$$y'' + w^2 y = g(t, y), \quad y(t_0) = y_0, \quad y'(t_0) = y'_0, \tag{1}$$

where the magnitude of the perturbing force satisfies $\|g(t, y)\| \leq \|y\|$. This type of problems arise in different scientific areas such as celestial mechanics, nuclear physics, quantum chemistry, electronics, and so on. In this talk, we investigate the construction of an adapted explicit four-step method adapted to the numerical integration of perturbed oscillators. The new derived method has simple structure, has algebraic order six, and can integrate the harmonic oscillator without truncation error.

 ISBN: 978-84-608-6082-2

2 Construction of an adapted explicit four-step method

The variation-of-constant formula for (1) reads

$$y(t_n+h)=y(t_n)\cos(v)+hy'(t_n)\frac{\sin(v)}{v}+h^2\int_0^1\hat{g}(t_n+hz)\frac{\sin(v(1-z))}{v}\mathrm{d}z, \tag{2}$$

where $v=wh$ and $\hat{g}(t)=g(t,y(t))$. Suppose that $\hat{g}(t)$ is smooth enough we can write

$$\hat{g}(t_n+hz)=\sum_{j=0}^{\infty}h^j\hat{g}^{(j)}(t_n)\frac{z^j}{j!}. \tag{3}$$

Substituting the equation in (2), the exact solution of (1) can be expressed in terms of the ϕ-functions

$$y(t_n+h)=y(t_n)\phi_0(v)+hy'(t_n)\phi_1(v)+\sum_{j=0}^{\infty}h^{j+2}\hat{g}^{(j)}(t_n)\phi_{j+2}(v). \tag{4}$$

where

$$\phi_0(v)=\cos(v),\phi_1(v)=\frac{\sin(v)}{v},\phi_{j+2}(v)=\int_0^1\frac{\sin(v(1-z))}{v}\frac{z^j}{j!}\mathrm{d}x,j\geqslant 0.$$

For interesting properties of the ϕ-functions, the reader is referred to You et al. [12] and Gonzlez et al. [5] .

Keeping in mind that $\phi_j(v)$ is an even function [10], we substitute the step size h with $2h$ and $-2h$ respectively in (4) and get

$$\begin{aligned}y(t_n+2h)&=y(t_n)\phi_0(2v)+2hy'(t_n)\phi_1(2v)+\sum_{j=0}^{\infty}(2h)^{j+2}\hat{g}^{(j)}(t_n)\phi_{j+2}(2v),\\ y(t_n-2h)&=y(t_n)\phi_0(2v)-2hy'(t_n)\phi_1(2v)+\sum_{j=0}^{\infty}(-2h)^{j+2}\hat{g}^{(j)}(t_n)\phi_{j+2}(2v).\end{aligned} \tag{5}$$

Adding the two equations in (5), we obtain

$$y(t_n+2h)+y(t_n-2h)=2y(t_n)\phi_0(2v)+2\sum_{j=0}^{\infty}(2h)^{2j+2}\hat{g}^{(2j)}(t_n)\phi_{2j+2}(2v). \tag{6}$$

The derivatives $\hat{g}^{(2)}(t_n),\hat{g}^{(4)}(t_n)$ in (6) can be approximated by the finite difference formulae

$$\begin{aligned}\hat{g}^{(2)}(t_n)&=\frac{-\hat{g}(t_n-2h)+16\hat{g}(t_n-h)+16\hat{g}(t_n+h)-\hat{g}(t_n+2h)-30\hat{g}(t_n)}{12h^2}+\mathcal{O}(h^4),\\ \hat{g}^{(4)}(t_n)&=\frac{\hat{g}(t_n-2h)-4\hat{g}(t_n-h)-4\hat{g}(h+t_n)+\hat{g}(2h+t_n)+6\hat{g}(t_n)}{h^4}+\mathcal{O}(h^2).\end{aligned}$$

 ISBN: 978-84-608-6082-2

Thus we have the following express

$$\begin{aligned} & y\left(t_n+2h\right)+y\left(t_n-2h\right)-2y(t_n)\phi_0(2v) \\ & = h^2\left(\left(128\phi_6(2v)-\tfrac{8}{3}\phi_4(2v)\right)\left(\hat{g}(t_n-h)+\hat{g}(t_n+h)\right)\right. \\ & \quad +\left(\tfrac{128}{3}\phi_4(2v)-512\phi_6(2v)\right)\left(\hat{g}(t_n-2h)+\hat{g}(t_n+2h)\right) \\ & \quad \left.+\left(768\phi_6(2v)+8\phi_2(2v)-80\phi_4(2v)\right)\hat{g}(t_n)\right)+\mathcal{O}(h^8). \end{aligned} \tag{7}$$

Based on the equation (7), we propose a symmetric four-step sixth-order method for the perturbed oscillator (1) in the following form

$$y_{n+2}+a_1y_n+y_{n-2}=h^2\left(b_1\left(g_{n+2}+g_{n-2}\right)+b_2\left(g_{n+1}+g_{n-1}\right)+b_3g_n\right) \tag{8}$$

where

$$\begin{aligned} a_1 &= -2\phi_0(2v), & b_1 &= 128\phi_6(2v)-\tfrac{8}{3}\phi_4(2v), \\ b_2 &= \tfrac{128}{3}\phi_4(2v)-512\phi_6(2v), & b_3 &= 768\phi_6(2v)+8\phi_2(2v)-80\phi_4(2v). \end{aligned}$$

For small values of $|v|$ the above formulae are subjected to heavy cancellations, then the following Taylor series expansions should be used:

$$\begin{aligned} a_1 &= -2+4v^2-\frac{4v^4}{3}+\frac{8v^6}{45}-\frac{4v^8}{315}+\frac{8v^{10}}{14175}-\frac{8v^{12}}{467775}+\cdots, \\ b_1 &= \frac{1}{15}+\frac{2v^2}{945}-\frac{v^4}{2025}+\frac{2v^6}{66825}-\frac{134v^8}{127702575}+\frac{16v^{10}}{638512875}+\cdots, \\ b_2 &= \frac{16}{15}-\frac{176v^2}{945}+\frac{208v^4}{14175}-\frac{64v^6}{93555}+\frac{544v^8}{25540515}-\frac{304v^{10}}{638512875}+\cdots, \\ b_3 &= \frac{26}{15}-\frac{304v^2}{315}+\frac{706v^4}{4725}-\frac{592v^6}{51975}+\frac{892v^8}{1702701}-\frac{3448v^{10}}{212837625}+\cdots. \end{aligned}$$

It is observed that when $v\to 0$, this adapted method reduces to the classical Störmer-Cowell implicit four-step method [6].

The scheme (8) is implicit. At each step a nonlinear algebraic system must be solved by, for example, the Newton-Raphson iteration in order to find y_{n+2} so that the computational cost is expensive. As a recipe, we use a explicit symmetric four-step Störmer-Cowell method [6] as a predictor for an approximation of y_{n+2} and then correct the result with (8). Thus an adapted explicit four-step method is obtained in the following form

$$\begin{aligned} \bar{y}_{n+2} &= h^2\left(\frac{7}{6}(g_{n+1}-w^2y_{n+1})-\frac{1}{3}(g_n-w^2y_n)+\frac{7}{6}(g_{n-1}-w^2y_{n-1})\right), \\ y_{n+2}+a_1y_n+y_{n-2} &= h^2\left(b_1\left(\bar{g}_{n+2}+g_{n-2}\right)+b_2\left(g_{n+1}+g_{n-1}\right)+b_3g_n\right), \end{aligned} \tag{9}$$

where $\bar{g}_{n+2}=g(t_{n+2},\bar{y}_{n+2})$. The algebraic order of the adapted explicit four-step method (9) is of sixth and the principal term of the local truncation error is given by

$$LTE=\frac{1}{37800}h^8\left(y^{(6)}\left(189g_y-80w^2\right)-80y^{(8)}\right)$$

 ISBN: 978-84-608-6082-2

The new explicit method defined by (9) is denoted as AFS. It is observable that the adapted explicit method is capable of integrating exactly the harmonic oscillator. i.e. the equation(1) with $g(t, y) = 0$).

3 Numerical illustrations

In order to show the accuracy and efficiency of the new adapted method derived above, two model problems are considered. Five two-step or four-step methods are selected from the literature for comparison. The efficiency is measured by the decimal logarithm of the maximum global error ($\text{Log}_{10}|\text{ERR}|$) vesus the computational effort measured by the number of function evaluations (NEF) required by each method. The methods used in the numerical comparison are listed as follows:

- FS: Classical explicit four-step method with the free parameter $c_1 = -1/10$ based on [1].
- SFS: Explicit four-step method with the phase-lag and its first and second derivatives vanished developed in [8].
- SFSH: Explicit hybrid four-step method with the phase-lag and its first, second and third derivatives vanished developed in [9].
- TS: Classical explicit two-step method proposed in [2].
- ATS: Adapted explicit two-step method developed in [10].
- AFS: The new adapted explicit four-step method (9) derived in this paper.

Problem 1. We consider "almost" periodic problem

$$y''(x) + 169y(x) = (480 - 160i)e^{3ix}, \quad y(0) = 4 + i, \quad y'(0) = -23 + 22i,$$

or equivalently by

$$\begin{aligned} u''(x) + 169u(x) &= 480\cos(3x) + 160\sin(3x), \\ v''(x) + 169v(x) &= 480\sin(3x) - 160\cos(3x), \\ u(0) = 4, u'(0) &= -23, v(0) = 1, u'(0) = 22. \end{aligned}$$

The analytic solution is

$$y(x) = u(x) + \mathrm{i}v(x),$$

with

$$\begin{aligned} u(x) &= 3\cos(3x) + \cos(13) + \sin(3x) - 2\sin(13x), \\ u(x) &= -\cos(3x) + 2\cos(13) + 3\sin(3x) + \sin(13x). \end{aligned}$$

 ISBN: 978-84-608-6082-2

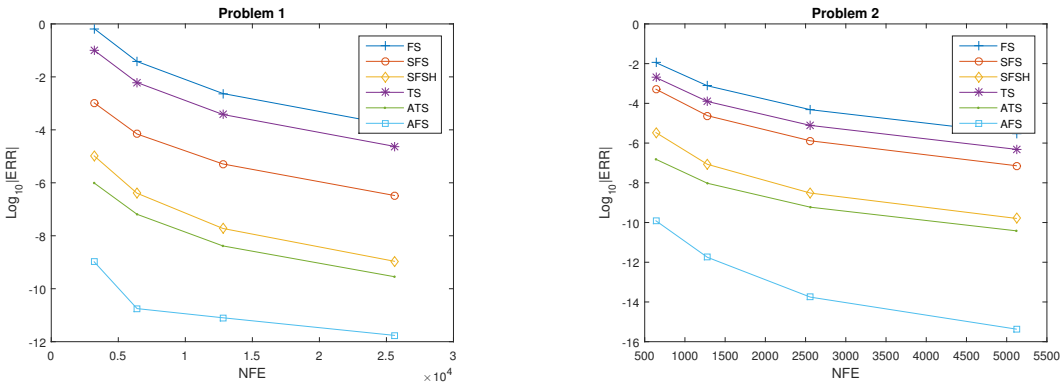

Figure 1: Efficiency comparison

In our test we choose $w = 13$, and the equation has been integrated in the interval $[0, 100]$.
Problem 2. A linear test problem was studied by Franco [3]

$$y'' + w^2 y = (w^2 - 4t^2)\cos(t^2) - 2\sin(t^2), \quad y(0) = 1, \quad y'(0) = w,$$

the analytic solution is given by

$$y(t) = \sin(wt) + \cos(t^2).$$

In our test we choose the integration interval $[0, 5]$, and the parameter (also is the estimated frequency) $w = 50$.

Figure 1 depicts the efficiency curves for the above two problems. We see that the new adapted method AFS outperforms the other five methods.

4 Conclusions

In this paper, an adapted explicit hybrid four-step method based on the algorithm of Scheifele which is derived by refining the classical Taylor expansion. The good property of Scheifele's based methods is that they can integrate exactly unperturbed oscillator, we give the principal local truncation error (PLTE) of the new adapted method which also confirms this fact. The analysis of phase-lag and linear stability property is made and discussed. The numerical experiments show that the new adapted method is much more accurate and efficient than some well-known methods proposed in the scientific literature. Finally, we should note that the new adapted method depend on the fitted frequency, a good estimate of the dominant frequency is needed for the adapted method to be applied effectively. For the choice of the fitting frequency, the reader is referred to the papers [11, 7].

Two-Derivative Runge-Kutta Method with increased phase-lag and dissipation order for the Schödinger equation

Ping Wang[1] **and Yonglei Fang**[1]

[1] *School of Mathematics and Statistics, Zaozhuang University*

emails: happywpnn@sohu.com, ylfangmath@163.com

Abstract

Optimized explicit two-derivative Runge-Kutta (TDRK) method with increased phase-lag and dissipation order for the numerical integration of the Schrödinger equation is constructed in this paper. The methods is of order five with increased order of phase and dissipation. Numerical results are reported to show the efficiency of the new method.

Key words: TDRK method, Schrödinger equation, Phase-lag, Dissipation.
MSC 2000: 65L05

1 Introduction

In this paper, we are concerned with the numerical integration of the Schrödinger equation of the form

$$y''(x) = \big(V(x) - E\big)y(x), \tag{1}$$

where the real number E is the *energy* and the function $V(x)$ is the *effective potential* satisfying $V(x) \to 0$ as $x \to \infty$. Regarding the oscillatory feature of the problem (1), researchers have proposed many numerical methods with frequency-dependent coefficients by some techniques such as trigonometrical/exponential fitting.

In [1], Kosti et al. constructed optimized constant coefficients Runge-Kutta method with increased phase-lag order for the numerical integration of the Schrödinger equation.

In this paper we construct an optimized explicit TDRK method with optimized phase-lag and dissipation for the numerical integration of Schrödinger equation based on the TDRK methods in [2].

 ISBN: 978-84-617-8694-7

2 Basic Theory

2.1 Two-derivative Runge-Kutta methods

For the numerical integration of (1), we consider the following explicit TDRK methods in [2] of the form,

$$\begin{cases} Y_1 = y_n, \\ Y_k = y_n + c_k h f(x_n, y_n) + h^2 \sum_{j=1}^{k-1} a_{kj} g(x_n + c_j h, Y_j), \ k = 2, \ldots, s, \\ y_{n+1} = y_n + h f(x_n, y_n) + h^2 \sum_{k=1}^{s} b_k g(x_n + c_k h, Y_k), \end{cases} \tag{2}$$

in which $g(x, y) := y''(x) = \frac{\partial}{\partial x} f(x, y) + \frac{\partial}{\partial y} f(x, y) \cdot f(x, y)$. The method (2) can be expressed briefly by the Butcher tableau

$$\begin{array}{c|c} c & A \\ \hline & b^T \end{array} = \begin{array}{c|cccc} 0 & & & & \\ c_2 & a_{21} & & & \\ \vdots & \vdots & \ddots & & \\ c_s & a_{s1} & \ldots & a_{ss-1} & \\ \hline & b_1 & \cdots & b_{s-1} & b_s \end{array}$$

or simply by (c, A, b). As the scheme (2) indicates, at each step, this special explicit TDRK method involves only one evaluation of the function f and s evaluations of the function g. The order conditions for the general-purpose TDRK method (2) are given in Chan et. al in [2].

2.2 Phase-lag property of the TDRK methods

For the purpose of phase analysis, we consider the following test equation

$$y' = \mathrm{i}\omega y, \quad \mathrm{i}^2 = -1, \tag{3}$$

in which $\omega > 0$ is the frequency of the problem. Applying the TDRK method (2) to (3) yields

$$y_{n+1} = M(\nu) y_n, \quad \nu = \omega h, \tag{4}$$

where $M(\nu)$ is called the stability function.

Definition 2.1 *(see [3]) For the TDRK method (2) with stability function $M(\nu)$, the quantities*

$$PL(\nu) = \nu - \arg(M(\nu)), \quad DIS(\nu) = 1 - |M(\nu)| \tag{5}$$

 ISBN: 978-84-617-8694-7

are called phase-lag and dissipation. If

$$PL(\nu) = c_\phi \nu^{q+1} + \mathcal{O}(\nu^{q+3}), DIS(\nu) = c_d \nu^{p+1} + \mathcal{O}(\nu^{p+3}),$$

the method is said to have phase-lag order q and dissipation order p, respectively.

Denoting $M(\nu) = U(\nu) + \mathrm{i}V(\nu)$ with $U(\nu),\ V(\nu)$ the real and imaginary parts of $M(\nu)$, we have

$$U(\nu) = 1 - \nu^2 b^T (I + \nu^2 A)^{-1} e, \quad V(\nu) = \nu\big(1 - \nu^2 b^T (I + \nu^2 A)^{-1} c\big).$$

The phase-lag and the dissipation become

$$PL(\nu) = \nu - \arctan\left(\frac{V(\nu)}{U(\nu)}\right), \quad DIS(\nu) = 1 - \sqrt{V^2(\nu) + U^2(\nu)} \tag{6}$$

Theorem 2.1 *([4]) For the TDRK method given by (2), we have the following formula for the direct calculation of the phase-lag order p and the phase-lag constant c_ϕ*

$$\tan(\nu) - \frac{V(\nu)}{U(\nu)}) = c_\phi \nu^{p+1}.$$

3 Construction of the new method

In this section, we shall give a new kind of TDRK method with increased phase-lag order and dissipation order. We consider the four stages explicit TDRK method which is simplify denoted by the Butcher tableau

$$\begin{array}{c|cccc} 0 & & & & \\ c_2 & a_{21} & & & \\ c_3 & a_{31} & a_{32} & & \\ c_4 & a_{41} & a_{42} & a_{43} & \\ \hline & b_1 & b_2 & b_3 & b_4 \end{array} \tag{7}$$

Together with the simplified assumptions $Ae = c^2/2$. Applying this method to the test equation (3), we have

$$y_{n+1} = (U(\nu) + \mathrm{i}V(\nu)) y_n, \quad \nu = \omega h, \tag{8}$$

in which

$$U(\nu) = 1 - \nu^2 s_1 + \nu^4 s_2 - \nu^6 s_3 + \nu^8 s_4,$$

$$V(\nu) = \nu - \nu^3 u_1 + \nu^5 u_2 - \nu^7 u_3,$$

 ISBN: 978-84-617-8694-7

with $s_k = b^T.A^{k-1}.e(k = 1, 2, 3, 4), u_j = b^T.A^{j-1}.c(j = 1, 2, 3)$. We have the following Taylor series

$$\begin{aligned} \frac{V(\nu)}{U(\nu)} &= \phi_3\nu^3 + \phi_5\nu^5 + \phi_7\nu^7 + \phi_9\nu^9 + \phi_{11}\nu^{11} + \cdots, \\ DIS(\nu) &= d_2\nu^2 + d_4\nu^4 + d_6\nu^6 + d_8\nu^8 + \cdots, \end{aligned} \tag{9}$$

in which

$$\phi_3 = (u_1 - s_1), \phi_5 = -s_1^2 + s_2 + s_1u_1 + u_2,$$

$$\phi_7 = -s_1^2(s_1 + u_1) - s_3 - s_2u_1 - s_1(u_2 - 2s_2) + u_3,$$

$$\phi_9 = s_1^2(3s_2 - u_2 + u_1s_1 - s_1^2) + s_2(u_2 - s_2) + s_4 + s_3u_1 + s_1(u_3 - 2s_3 - 2s_2u_1),$$

$$\phi_{11} = s_1^3(4s_2 - u_2 + s_1u_1 - s_1^2) + 2s_2s_3 + s_2u_1 - s_4u_1 - s_3u_2 - s_2u_3$$
$$+s_1(2s_2u_2 + 2(s_4s_3u_1) - 3s_2^2) + s_1^2(u_3 - 3s_3 - 3s_2u_1),$$

$$d_2 = (2s_1 - 1)/2, d_4 = (1 - 4s_1 - 8s_2 + 8u_1)/8,$$

$$d_6 = (8(s_2 - s_1 - u_1 + 2s_3 + 2s_1u_1 - 2u_2) - 1 + 6s_1)/16,$$

$$d_8 = (16(3u_1 - s_2(3 + 8u_1)) - 40s_1 - 64(s_1^3 + s_3 + 3s_1u_1 + s_1u_1^2 + u_2)$$
$$+32(3u_1^2 + 3s_1^2) + 128(s_1^2u_1 - s_4 + s_1s_2 - s_1u_2 + u_1u_2 + u_3) - 5)/128.$$

We solve the fifth order equations and get

$$a_{32} = (2a_{43}c_3(3 - 5(c_2 + c_3 - 2c_2c_3)) + 2a_{42}c_2(3 - 5(c_3 - c_2(2c_3 - 1)))$$
$$+c_4(c_2-_4)(c_4 - c_3))(c_2 - c_3)c_3/(2c_2(c_2 - c_4)c_4(3 - 5c_4 + 5c_2(2c_4 - 1))),$$

$$b_4 = \frac{3 - 5c_3 + 5c_2(2c_3 - 1)}{60c_4(c_4 - c_2)(c_4 - c_3)}, \quad b_3 = \frac{-3 + 5c_4 + c_2(5 - 10c_4)}{60(c_2 - c_3)c_3(c_3 - c_4)}, a_{21} = c_2^2/2,$$

$$b_2 = \frac{3 - 5c_4 + 5c_3(2c_4 - 1)}{60c_2(c_2 - c_3)(c_2 - c_4)}, b_1 = \frac{1}{2} - b_2 - b_3 - b_4,$$

$$a_{31} = c_3^2/2 - a_{32}, a_{41} = c_4^2/2 - a_{42} - a_{43}.$$

There are five parameters in the new five order TDRK method, the choice of the free paremeters is very essential for the oscillatory systems. We select optimized parameters so that the dispersion and the dissipation are minimal.

 ISBN: 978-84-617-8694-7

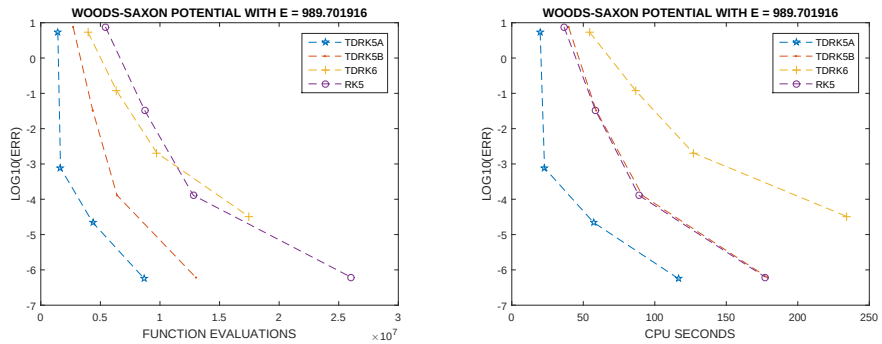

Figure 1: Efficiency curves for $E = 989.701916$

Case(I): Selecting the parameters such that the dispersion to be order twelve. Solving $\phi_7 = \frac{17}{315}, \phi_9 = \frac{62}{2835}, \phi_{11} = \frac{1382}{155925}$ yields $c_2 = \frac{1}{7}$ and

$$\begin{aligned} a_{43} &= \frac{127(c_3 - c_4)c_4(7c_4 - 1)}{198c_3(16 - 137c_3 + 175c_3^2)}, \\ a_{42} &= \frac{7c_4(7c_4 - 1)(6336 + 88011c_3^2 + 18802c_4 - c_3(73054 + 18711c_4))}{25146(7c_3 - 1)(25c_3 - 16)}. \end{aligned} \tag{10}$$

The proposed TDRK method with free parameter $c_3,\ c_4$. We try to get an optimal method minimizing the error constant

$$C^{(6)} = \left((\tau_1^{(6)})^2 + (\tau_2^{(6)})^2 + (\tau_3^{(6)})^2\right)^{1/2} \tag{11}$$

in which $\tau_i^{(6)}$ are the error constants of a five-order TDRK method. We minimize the errr constant (11) and obtain $c_3 = \frac{101}{254}, c_4 = \frac{62}{81}$. The method is of phase-lag order twelve and dissipation order five. We denote this method as TDRK5-12-5 and the method is list as

$$\begin{array}{c|cccc} 0 & & & & \\ \frac{1}{7} & \frac{1}{98} & & & \\ \frac{101}{254} & \frac{14443}{16387064} & \frac{320271}{4096766} & & \\ \frac{62}{81} & \frac{827410679635}{8178059102301} & \frac{316504531259}{36679809637053} & \frac{678470997055292}{3704660773342353} & \\ \hline & \frac{6187}{125240} & \frac{1611071}{9594540} & \frac{1040578564}{5193194265} & \frac{272629233}{3312227240} \end{array} \tag{12}$$

4 Numerical Illustrations

In this section, we shall examine the numerical performance of the new method. The methods we choose for comparison are as follows:

- TDRK5A: the optimized sixth order TDRK method derived in this paper. .
- TDRK6: the sixth order TDRK method with $c_4 = 1$ given in [2].
- TDRK5B: the fifth order TDRK method derived in [5].
- RK5: the optimized fifth order RK method derived by Kosti in [1].

We consider the numerical integration of the Schrödinger equation (1) with the well-known Woods-Saxon potential of the form in [3]

$$V(x) = c_0 z\big(1 - a(1-z)\big),$$

where $z = \Big(\exp\big(a(x-b)+1\big)\Big)^{-1}$, $c_0 = -50,\ a = 5/3,\ b = 7$. We solve the problem on the interval $[0, 15]$.

In the numerical experiments, we consider the so-called resonant-state problem $E > 0$, that is to find the energies (or resonances) $E \in [0, 1000]$ for which the phase shift is equal to $\frac{\pi}{2}$. The boundary conditions for this problem are

$$y(0) = 0 \quad \text{and} \quad y(x) = \cos(\sqrt{E}x) \quad \text{for large } x.$$

In Fig. 1, we plot the logarithm of error $|E_{\text{analytical}} - E_{\text{calculated}}|$ (LOG(ERR)) versus the computational effort by the number of function evaluations (FUNCTION EVALUATIONS) and the cpu times (CPU SECONDS) required by each methods for $E_{\text{analytical}} = 989.701916$. In view of Fig.1, we observe that the new method TDRKA shows more advantage over the selected methods.

Abstract

A family of modified two-derivative Runge-Kutta (MTDRK) methods for the integration of Schrödinger equation are obtained. These methods are of algebraically order five. The numerical results in the integration of the radial Schrödinger equation with the Woods-Saxon potential are reported to show the high efficiency of our new methods. The result of error analysis is confirmed by the resonance problem.

1 Introduction

In this paper we are focused on the numerical integration of one-dimensional Schrödinger equation of the form

$$y''(x) = \big(W(x) - E\big)y(x), \tag{1}$$

where the real number E is the *energy* and the function $W(x)$ is the *effective potential* satisfying $W(x) \to 0$ as $x \to \infty$. Two boundary conditions are associated with this equation: one is $y(0) = 0$ and the other imposed at large x is determined by physical considerations. The form of this second boundary condition depends crucially on the sign of the energy E.

Inspired by the ideas of Van de Vyver [1, 2], the purpose of this paper is to construct practical optimized modified TDRK methods for the numerical integration of the radial Schrödinger equation (1).

 ISBN: 978-84-617-8694-7

2 Modified TDRK methods and order conditions

We begin with consideration of an initial value problem of systems of first-order differential equations in the form

$$y'(x) = f(x, y), \quad y(x_0) = y_0, \tag{2}$$

whose solution has an oscillatory character, where $y \in \mathbb{R}^d$, $f : \mathbb{R} \times \mathbb{R}^d \to \mathbb{R}^d$ is a smooth function. Regarding the oscillatory property of the solution of the problem (2), we consider the following special form of explicit *modified TDRK method* [3]

$$\begin{cases} Y_1 = y_n, \\ Y_i = y_n + c_i h f(x_n, y_n) + h^2 \sum\limits_{j=1}^{i-1} a_{ij} g(x_n + c_j h, Y_j), \quad i = 2, \cdots, s, \\ y_{n+1} = y_n + h\beta(\nu) f(x_n, y_n) + h^2 \sum\limits_{i=1}^{s} b_i(\nu) g(x_n + c_i h, Y_i), \end{cases} \tag{3}$$

where c_i, a_{ij} $(1 \le j < i \le s)$ are real constants, $\beta(\nu)$ and $b_i(\nu)$ $(1 \le i \le s)$ are real even functions of $\nu = h\omega$ with ω an estimate of the principal frequency of the problem.

The scheme (3) can also be expressed compactly by the Butcher tableau

$$\begin{array}{c|c} c & A \\ \hline \beta(\nu) & b^T(\nu) \end{array} = \begin{array}{c|cccc} 0 & & & & \\ c_2 & a_{21} & & & \\ \vdots & \vdots & \ddots & & \\ c_s & a_{s1} & \cdots & a_{ss-1} & \\ \hline \beta(\nu) & b_1(\nu) & \cdots & b_{s-1}(\nu) & b_s(\nu) \end{array}$$

or simply by $(c, A, \beta(\nu), b(\nu))$. We assume that as $\beta(\nu) \to 1$ as $\omega \to 0$ so that when $\omega \to 0$ the modified RK method (3) reduces to a traditional two-derivative RK method with constant coefficients (see [3]).

3 Construction of new modified TDRK methods

Our aim is to determine the b-values and β-value in the scheme (3). Following the approach in [1, 2], we apply the method to the linear scalar equation

$$y' = \mathrm{i}\omega y, \quad y(x_0) = y_0, \quad \omega \in \mathbb{R}^+, \quad \mathrm{i}^2 = -1 \tag{4}$$

and obtain the recursive relation

$$y_1 = R(\nu) y_0, \tag{5}$$

where

$$R(\nu) = 1 + \mathrm{i}\nu\beta(\nu) + b(\nu)^T (I_s + \nu^2 A)^{-1} (e + \mathrm{i}\nu c)$$

 ISBN: 978-84-617-8694-7

is called the *stability function*. For the explicit scheme (3)

$$R(\nu) = U(\nu) + \mathrm{i}V(\nu)$$

where

$$\begin{aligned} U(\nu) &= 1 + b(\nu)^T(I_s - \nu^2 A + \nu^4 A^2 - \ldots + (-1)^{s-1}\nu^{2(s-1)}A^{s-1})e, \\ V(\nu) &= \nu\beta(\nu) + \nu b(\nu)^T(I_s - \nu^2 A + \nu^4 A^2 - \ldots + (-1)^{s-1}\nu^{2(s-1)}A^{s-1})c. \end{aligned} \tag{6}$$

In the sequel we consider a three-stage explicit modified TDRK given by

$$c_2 = \frac{3}{10}, a_{21} = \frac{9}{200}, c_3 = \frac{3}{4}, a_{31} = 0, a_{42} = \frac{9}{32}.$$

For this method,

$$R(\nu) = 1 + \sum_{j=1}^{6} r_j(\mathrm{i}\nu)^j, \tag{7}$$

where

$$r_1 = \beta(\nu), \quad r_2 = \sum_i b_i, \quad r_3 = \sum_i b_i c_i, \quad r_4 = \sum_{i,j} b_i a_{ij}, \quad r_5 = b_3 a_{32} c_2, \quad r_6 = b_3 a_{32} a_{21}.$$

Then the fitting condition becomes

$$U(\nu) = 1 - r_2\nu^2 + r_4\nu^4 - r^6\nu^6 = \cos(\nu), \quad V(\nu) = r_1\nu - r_3\nu^3 + r_5\nu^5 = \sin(\nu). \tag{8}$$

We choose the values A and c from the modified TDRK (3) and we get two linear equations in four unknowns $b_i(\nu),\ i = 1, 2, 3$ and $\beta(\nu)$. For the determination of these unknown parameters, we consider two different choices.

3.1 The first optimized modified TDRK method

Together with the order conditions

$$b_1(\nu) + b_2(\nu) + b_3(\nu) = \frac{1}{2}, \quad b_2(\nu)c_2 + b_3(\nu)c_3 = \frac{1}{6}, \tag{9}$$

we solve equations (8) and derive the following solution

$$\begin{aligned} \beta(\nu) &= \tfrac{10\nu^3 - 60\nu(1-\cos(\nu)) + \sin(\nu)(9\nu^2-120)}{9\nu^3 - 120\nu}, \\ b_1(\nu) &= \tfrac{6400 - 3200\nu^2 + 200\nu^4 - 3\nu^6 - 6400\cos(\nu)}{54\nu^6 - 720\nu^4}, \\ b_2(\nu) &= \tfrac{5(1600\nu^2 - 3200(1-\cos(\nu)) - 200\nu^4 + 9\nu^6)}{27\nu^4(3\nu^2-40)}, \\ b_3(\nu) &= \tfrac{160(40 - 20\nu^2 + \nu^4 - 40\cos(\nu))}{27\nu^4(3\nu^2-40)}. \end{aligned}$$

 ISBN: 978-84-617-8694-7

It is easy to check that

$$\beta(\nu) = 1 - \frac{\nu^6}{100800} + \mathcal{O}(\nu^8),\ b(\nu)^T c^2 = \frac{1}{12} - \frac{\nu^2}{3600} + \mathcal{O}(\nu^4),$$
$$b(\nu)^T c^3 = \frac{1}{20} - \frac{7\nu^2}{24000} + \mathcal{O}(\nu^4),\ b(\nu)^T Ac = \frac{1}{120} - \frac{\nu^2}{14400} + \mathcal{O}(\nu^4).$$

Therefore the new method is of order five and we denote this method as MTDRK5I.

3.2 The second optimized modified TDRK method

Another approach is to consider two linear equations of the form (4) with frequencies $\omega = \omega_1$ and $\omega = \omega_2$, respectively. Then substituting $\nu = \nu_1 = \omega_1 h$ and $\nu = \nu_2 = \omega_2 h$ in the equations (8), we obtain a system of four linear equations in the four parameters $b_i(\nu)$, $i = 1, 2, 3$ and $\beta(\nu)$. The solutions b_i, $i = 1, 2, 3$ and β contain two parameters ν_1 and ν_2. Taking the limits $\nu_1 \to \nu$ and $\nu_2 \to \nu$, we get

$$\beta(\nu) = \frac{40\nu - 80\nu\cos(\nu) + 3\nu^3\cos(\nu) + 120\sin(\nu) - 23\nu^2\sin(\nu)}{80\nu},$$
$$b_3(\nu) = \frac{4(40 + (3\nu^2 - 40)\cos(\nu) - 23\nu\sin(\nu))}{27\nu^4},$$
$$b_2(\nu) = \frac{40(9\nu^2 - 40) + \cos(\nu)(1600 - 660\nu^2 + 27\nu^4) + (1100\nu - 207\nu^3)\sin(\nu)}{108\nu^4},$$
$$b_1(\nu) = (40(3200 - 480\nu^2 + 27\nu^4) + (52800\nu^2 - 128000 - 4680\nu^4 + 81\nu^6)\cos(\nu)$$
$$-\nu(97600 - 20400\nu^2 + 621\nu^4))/(14400\nu^4).$$

Again it is easy to check that

$$\beta(\nu) = 1 + \frac{13\nu^6}{50400} + \mathcal{O}(\nu^8),\ b(\nu)^T e = \frac{1}{2} - \frac{\nu^4}{720} + \mathcal{O}(\nu^6),$$
$$b(\nu)^T c = \frac{1}{6} + \frac{\nu^4}{3150} + \mathcal{O}(\nu^6),\ b(\nu)^T c^2 = \frac{1}{12} - \frac{\nu^2}{1800} + \mathcal{O}(\nu^4),$$
$$b(\nu)^T c^3 = \frac{1}{20} - \frac{7\nu^2}{12000} + \mathcal{O}(\nu^4),\ b(\nu)^T Ac = \frac{1}{120} - \frac{\nu^2}{7200} + \mathcal{O}(\nu^4).$$

Therefore the new method is of order five and we denote this method as MTDRK5II.

4 Numerical results

In this section, we test the numerical performance of the new fifth-order modified TDRK methods in the integration of the radial Schrödinger equation with the Woods-Saxon potential. The methods we choose for comparison are as follows:

- EFTDRK4I: optimized TDRK method with order four derived by Fang et al. in [5]
- EFTDRK4II: optimized TDRK method with order four derived by Fang et al. in [5]
- RK5V: optimized RK method with order five derived by Van de Vyver in [6]

 ISBN: 978-84-617-8694-7

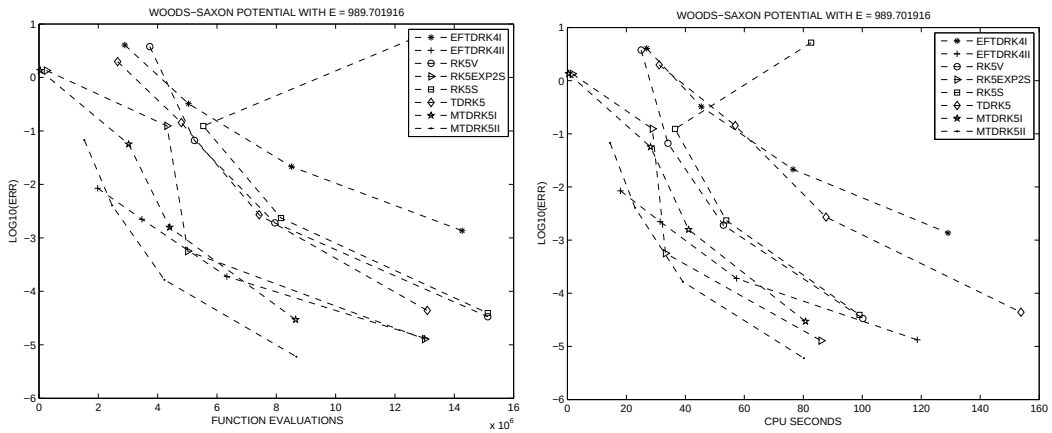

Figure 1: Efficiency curves for $E = 989.701916$

- RK5S: phase fitted RK method with order five presented by Simos in [7]
- RK5EXP2S: the exponentially fitted fifth order RK method with exponential order two presented by Simos in [4].
- TDRK5: the classical TDRK with order five in [3].
- MTDRK5I: modified optimized two-derivative fifth order RK method derived in Section 3.1.
- MTDRK5II: modified optimized two-derivative fifth order RK method derived in Section 3.2.

We consider the numerical integration of the Schrödinger equation (1) with the well-known Woods-Saxon potential

$$V(x) = c_0 z\big(1 - a(1-z)\big),$$

where $z = \Big(\exp\big(a(x-b)+1\big)\Big)^{-1}$, $c_0 = -50$, $a = 5/3$, $b = 7$. The problem is solved on the interval $[0, 15]$. In the numerical experiments, we consider the so-called resonant-state problem $E > 0$, that is, to find the energies (or resonances) $E \in [0, 1000]$ for which the phase shift is equal to $\frac{\pi}{2}$. The boundary conditions for this problem are

$$y(0) = 0 \quad \text{and} \quad y(x) = \cos(\sqrt{E}x) \quad \text{for large } x.$$

We follow the lines of [6, 8] and choose the fitted frequency

$$\omega = \begin{cases} \sqrt{50+E}, & x \in [0, 6.5], \\ \sqrt{E}, & x \in [6.5, 15]. \end{cases}$$

 ISBN: 978-84-617-8694-7

The numerical results $E_{\text{calculated}}$ are compared with the analytical solution $E_{\text{analytical}}$ of the Woods-Saxon potential, rounded to six decimal places. In Fig. 1, we plot the error $\log_{10}|E_{\text{analytical}} - E_{\text{calculated}}|$ versus the computational effort measured by the number of function evaluations (FUNCTION EVALUATIONS) and the CPU time (CPU SECONDS) required by each method for $E_{\text{analytical}}$=989.701916.

Abstract

A family of trigonometrically-fitted multi-derivative linear methods involving several derivatives for the numerical integration of the Schrödinger equation are obtained in this paper. Numerical results are reported to show the efficiency and robustness of the new method IV specially adapted to the integration of the radial time-independent Schrödinger equation for large energies.

Key words: Schrödinger equation, Obrechkoff method,Trigonometrically fitted.
MSC 2000: 65L05

1 Introduction

In this paper, we are interested in the numerical integration of one-dimensional Schrödinger equation of the form

$$y''(x) = \big(W(x) - E\big)y(x), \quad x \in [x_0, X], \tag{1}$$

where E is a real number representing the *energy*, the function $W(x)$ represents the *potential* with the property $W(x) \to 0$ as $x \to \infty$. In [1], by using trigonometric fitting, Wang derived a trigonometrically fitted Obrechkoff one-step method which is more accuracy and effective than the original method for the numerical solution of one-dimensional Schrödinger equation. This new method differs from the original Obrechkoff one-step method only in one simple coefficient. In this paper, we present a family of trigonometrically fitted one-step methods with multi-derivative of higher algebraic order than method in [1]. The numerical tests are carried out to show the efficiency of our new methods.

 ISBN: 978-84-617-8694-7

2 Multi-derivative linear methods with variable coefficients

Now we consider the one-step four-derivative linear methods of the Obrechkoff type in the form

$$\begin{aligned} y(x+h)-y(x) = hc_0\big(y'(x+h)+y'(x)\big) + h^2c_1\big(y''(x+h)-y''(x)\big) \\ +h^3c_2\big(y^{(3)}(x+h)+y^{(3)}(x)\big) + h^4c_3\big(y^{(4)}(x+h)+y^{(4)}(x)\big). \end{aligned} \tag{2}$$

If we choose $\{c_0,\ c_1,\ c_2,\ c_3\} = \{\frac{1}{2},\ -\frac{3}{28},\ \frac{1}{84},\ -\frac{1}{1680}\}$,we can derive Obrechkoff one step method of order seven which can be found in [2].In this section we will apply trigonometical fitting to the original one step method to construct more accuracy and efficient one step methods for the numerical solution of one-dimensional Schrodinger equation.

2.1 First new method

If we require the method (2) to integrate exactly the function $\exp(\mathrm{i}\omega x)$ ($\mathrm{i}^2=-1$), then we obtain

$$\cos(\frac{\nu}{2})(\nu^3c_2-\nu c_0)+\sin(\frac{\nu}{2})(1+c_1\nu^2-c_3\nu^4)=0, \quad \nu=\omega h. \tag{3}$$

With the choice $c_1=-\dfrac{3}{28}$ $c_2=\dfrac{1}{84}$ and $c_3=-\dfrac{1}{1680}$, solving the equation (3) yields

$$c_0=\frac{\nu^2}{84}+\left(\frac{1}{\nu}-\frac{3}{28}\nu^2+\frac{1}{1680}\nu^3\right)\tan(\frac{\nu}{2}). \tag{4}$$

We denote this method as method I. Its local truncation error is

$$LTE=-\frac{h^9}{25401600}\big(y^{(9)}(x)-\omega^8y'(x)\big)+\mathcal{O}(h^{10}).$$

2.2 Second new method

Now we set free the two coefficients $\{c_0,c_1\}$ and require that the method (2) to integrate exactly the functions

$$\{\exp(\mathrm{i}\omega x),\ x\exp(\mathrm{i}\omega x)\}, \tag{5}$$

leading to the following system of equations

$$\begin{cases} \cos(\frac{\nu}{2})(\nu^3c_2-\nu c_0)+\sin(\frac{\nu}{2})(1+c_1\nu^2-c_3\nu^4)=0, \\ \cos(\nu)(1-c_0+(c_1+3c_2)\nu^2-c_3\nu^4)+\sin(\nu)((c_0+2c_1)\nu-(c_2+4c_3)\nu^3)=-3c_2\nu^2+c_0. \end{cases} \tag{6}$$

 ISBN: 978-84-617-8694-7

Substituting$c_2 = \dfrac{1}{84}$ and $c_3 = -\dfrac{1}{1680}$ in (6) ,the following result emerges

$$\begin{aligned} c_0 &= \frac{1680 + 9\nu^4 - (1680 - \nu^4)\cos(\nu) - 10\nu^3\sin(\nu)}{840\nu(\nu + \sin(\nu))}, \\ c_1 &= -\frac{1680\nu + 40\nu^3 + \nu^5 + 40\nu^3\cos(\nu) - (1680 - 3\nu^4)\sin(\nu)}{1680\nu^2(\nu + \sin(\nu))}. \end{aligned} \tag{7}$$

We denote this method as method II. Its local truncation error is

$$LTE = -\frac{1}{25401600}\big(y^{(9)}(x) + 3\omega^8 y'(x) + 4\omega^6 y^{(3)}(x)\big)h^9 + \mathcal{O}(h^{10}).$$

2.3 Third new method

We free the three coefficients $\{c_0, c_1, c_2\}$ and keep the rest of c_3, then we demand the one-step method (2) to integrate exactly the functions

$$\{\exp(\mathrm{i}\omega x),\ x\exp(\mathrm{i}\omega x),\ x^2\exp(\mathrm{i}\omega x)\}.$$

We obtain the following equations

$$\begin{cases} \cos(\frac{\nu}{2})(\nu^3 c_2 - \nu c_0) + \sin(\frac{\nu}{2})(1 + c_1\nu^2 - c_3\nu^4) = 0, \\ \cos(\nu)(1 - c_0 + (c_1 + 3c_2)\nu^2 - c_3\nu^4) + 3c_2\nu^2 - c_0 \\ \quad + \sin(\nu)((c_0 + 2c_1)\nu - (c_2 + 4c_3)\nu^3) = 0, \\ \cos(\nu)(1 - 2c_0 - 2c_1 + (c_1 + 6c_2 + 12c_3)\nu^2 - c_3\nu^4) + 2c_1 - 12c_3\nu^2 \\ \quad + \sin(\nu)((c_0 + 4c_+6c_2)\nu - (c_2 + 8c_3)\nu^3) = 0. \end{cases} \tag{8}$$

Solving (8), we have

$$\begin{aligned} c_0 &= \frac{(-5040 - 3360\nu^2 - \nu^4 + 2\nu^6)\cos(\frac{\nu}{2}) + (5040 + \nu^4)\cos(\frac{3\nu}{2}) + \nu(16800\nu - 2\nu^5)\sin(\frac{\nu}{2})}{3360\nu(\nu\cos(\frac{\nu}{2}) - (1 - \nu^2 + \cos(\nu))\sin(\frac{\nu}{2}))}, \\ c_1 &= -\frac{(-5040\nu + 5\nu^5)\cos(\frac{\nu}{2}) + (1680 + \nu^4)(3 + \nu^2 + 3\cos(\nu))\sin(\frac{\nu}{2})}{1680\nu^2(\nu\cos(\frac{\nu}{2}) - (1 - \nu^2 + \cos(\nu))\sin(\frac{\nu}{2}))}, \\ c_2 &= \frac{(1680 - 3360\nu^2 + 3\nu^4 + 2\nu^6)\cos(\frac{\nu}{2}) - (1680 + 3\nu^4)(\cos(\frac{3\nu}{2}) - 2\nu\sin(\frac{\nu}{2}))}{3360\nu^3(\nu\cos(\frac{\nu}{2}) - (1 - \nu^2 + \cos(\nu))\sin(\frac{\nu}{2}))}. \end{aligned}$$

 ISBN: 978-84-617-8694-7

We denote this method as method III. Its local truncation error is

$$LTE = -\frac{1}{25401600}(y^{(9)}(x) - 8\omega^6 y^{(3)}(x) - 6\omega^4 y^{(5)}(x) - 3\omega^8 y'(x))h^9 + \mathcal{O}(h^{10}).$$

2.4 Fourth new method

Let $\{c_0, c_1, c_2, c_3\}$ are variable coefficients. We try to find the values of $\{c_0, c_1, c_2, c_3\}$ in such way that the one-step method (2) integrate exactly the functions

$$\{\exp(\mathrm{i}\omega x),\ x\exp(\mathrm{i}\omega x),\ x^2\exp(\mathrm{i}\omega x),\ x^3\exp(\mathrm{i}\omega x)\}.$$

We obtain the following equations

$$\begin{cases} \cos(\frac{\nu}{2})(\nu^3 c_2 - \nu c_0) + \sin(\frac{\nu}{2})(1 + c_1\nu^2 - c_3\nu^4) = 0, \\ \cos(\nu)(1 - c_0 + (c_1 + 3c_2)\nu^2 - c_3\nu^4) + \sin(\nu)((c_0 + 2c_1)\nu - (c_2 + 4c_3)\nu^3) + 3c_2\nu^2 - c_0 = 0, \\ \cos(x)(1 - 2c_0 - 2c_1 + (c_1 + 6c_2 + 12c_3)\nu^2 - c_3\nu^4) + \sin(\nu)((c_0 + 4c_+6c_2)\nu - (c_2 + 8c_3)\nu^3) \\ +2c_1 - 12c_3\nu^2 = 0, \\ \cos(\nu)(1 - 3c_0 - 6c_1 - 6c_2 + (c_1 + 9c_2 + 36c_3)\nu^2 - c_3\nu^4) + \sin(\nu)((c_0 + 6c_1 + 18c_2 + 24c_3)\nu \\ -(c_2 + 12c_3)\nu^3) - 6c_2 = 0. \end{cases} \tag{9}$$

Solving (9), we have

$$\begin{aligned} c_0 &= \frac{8(\nu(3 + 2\nu^2) + \cos(\nu)(-3\nu + \nu^3 - 3\sin(\nu)) + (3 - 6\nu^2)\sin(\nu))}{\nu(3 - 6\nu^2 + 2\nu^4 - 12\nu^2\cos(\nu) - 3\cos(2\nu) + 12\nu\sin(\nu) - 4\nu^3\sin(\nu))}, \\ c_1 &= -\frac{2(-9 + 18\nu^2 + 2\nu^4 + 24\nu^2\cos(\nu) + 9\cos(2\nu) - 24\nu\sin(\nu))}{\nu^2(3 - 6\nu^2 + 2\nu^4 - 12\nu^2\cos(\nu) - 3\cos(2\nu) + 12\nu\sin(\nu) - 4\nu^3\sin(\nu))}, \\ c_2 &= \frac{8(-3\nu + 2\nu^3 - 3\sin\nu + \cos(\nu)(3\nu + \nu^3 + 3\sin(\nu)))}{\nu^3(3 - 6\nu^2 + 2\nu^4 - 12\nu^2\cos(\nu) - 3\cos(2\nu) + 12\nu\sin(\nu) - 4\nu^3\sin(\nu))}, \\ c_3 &= \frac{-3 + 6\nu^2 - 2\nu^4 - 12\nu^2\cos(\nu) + 3\cos(2\nu) + 12\nu\sin(\nu) - 4\nu^3\sin(\nu)}{\nu^4(3 - 6\nu^2 + 2\nu^4 - 12\nu^2\cos(\nu) - 3\cos(2\nu) + 12\nu\sin(\nu) - 4\nu^3\sin(\nu))}. \end{aligned}$$

We denote this method as method IV. Its local truncation error is

$$LTE = -\frac{1}{25401600}(y^{(9)}(x) + 4\omega^2 y^{(7)}(x) + 6\omega^4 y^{(5)}(x) + 4\omega^6 y^{(3)}(x) + \omega^8 y'(x))h^9 + \mathcal{O}(h^{10}).$$

 ISBN: 978-84-617-8694-7

2.5 Formula for the first derivative

Because the Schrödinger equation (1) is linear, so all the high derivative $y^{(m)}$ at x can be expressed explicitly in terms of $y(x)$ and $y'(x)$ such as

$$y''(x) = f(x)y(x), \quad y^{(3)}(x) = f'(x)y(x) + f(x)y'(x),$$
$$y^{(4)}(x) = \big(f''(x) + f^2(x)\big)y(x) + 2f'(x)y'(x), \ldots$$

It is not sufficient for the problem (1) to have only formula (2). Therefore, we consider the following formula, which is obtain by differentiating (2) to x

$$\begin{aligned} y'(x+h) - y'(x) = hc_0\big(y''(x+h) + y''(x)\big) + h^2c_1\big(y^{(3)}(x+h) - y^{(3)}(x)\big) \\ +h^3c_2\big(y^{(4)}(x+h) + y^{(4)}(x)\big) + h^4c_3(y^{(5)}(x+h) - y^{(5)}(x)\big), \end{aligned} \tag{10}$$

where $c_0,\ c_1,\ c_2$ and c_3 are derived in this paper. Therefore, with the same ideas as in [1], we can compute the Schrödinger equation by combining (2) with (10).

3 Numerical experiment

In this section we carry out some numerical experiments to illustrate the performance of the new methods constructed in Section 2. We consider the numerical integration of the one-dimensional Schrödinger equation (1) with the Woods-Saxon potential

$$W(x) = c_0 z\big(1 - a(1-z)\big) \tag{11}$$

where $z = (\exp(a(x-b)+1))^{-1},\ c_0 = -50,\ a = 5/3,\ b = 7.$

For the test potential we shall consider the *resonance* problem consists in finding those eigenvalues (or energies) E in the range $1 \le E \le 1000$, at which the phase shift is equal $\pi/2$ with the domain $0 \le x \le 15$, and the initial phase is $\delta(E) = -\pi/2$. Basing on Quantum Mechanics [3], when $x \to \infty,\ v(x) \to 0$, the wave function has the following asymptotic expression

$$y(x) \to A\cos\big(\sqrt{E}x + \delta(E)\big). \tag{12}$$

In this test we choose $\omega = \sqrt{|W(x) - E|}$ and the exact eigenvalues are $E_{s8} = 53.588872, E_{s9} = 163.215341, E_{s10} = 341.495874, E_{s11} = 989.701916$.

In Figs. 1, we plot the decimal logarithm of the absolute error in 10^6 units versus the step-size with four eigenvalues among four methods I, II, III, IV.

From Figs.1, we can see that method IV are more superior to methods I , II and III. Among all the methods I, II, III and IV, method IV is the most efficient.

 ISBN: 978-84-617-8694-7

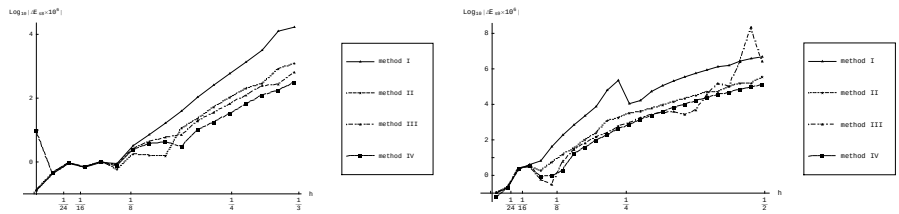

Figure 1: Efficiency curves for $E_{s8} = 53.588872$ and $E_{s9} = 163.215341$.
