Primer design

To design general primers for metabarcoding of predator gut content, it is necessary to reduce amplification of predator DNA. We approached this aim by examining potential mismatches between all major prey groups and the target spider groups. When locating suitable primers, it is not necessary to completely hinder amplification of predator DNA, only to reduce the amplification efficiency. Retaining some amplification of predator DNA even has the dual advantage that predator identity can be confirmed and that intraguild predation on closely related predators can be quantified.

To detect suitable primers, we used an approach similar to Lafage et al. (2020) where we downloaded all complete COI sequences from major prey groups (Hemiptera, Lepidoptera, Collembola, Hymenoptera, Coleoptera, Diptera) as well as from collected spider families (Philodromidae, Thomisidae, Theridiidae, Salticidae, Araneidae, Linyphidae, Dictynidae) and from opilionids. Downloaded sequences were aligned and cleaned using BioEdit (Hall 1999), and for each family we exported proportions of base pairs for each position. These proportions were plotted in Excel for visual comparisons of prey and predator sequences to identify sections with sequence mismatches between predators and all prey groups. Once, potential mismatches had been identified, the next steps were to examine that base pairs in either 3' or 5' direction showed less variation within and between prey groups and to include degenerate base pairs in some cases.

Through this process, we identified a set of four primers with potential to work for all included spider families and another set of four primers with potential to work for opilionids. We decided to focus on the two most promising primers for each set of predators (NoAranR: TGTCATCCDGTNCCWG; NoAranRa: TGDCCDACTGWCCTAAATRGGG; NoOpiR: GATCGTATATTAAATWAYWGTWGTAAATAAAATTTAC; NoOpiF: CCHGAYATAGCWTTYCCHCGAATA). As forward primer for NoAranR, NoAranRa and NoOpiR, we used LCO1490 (GGTCAACAAATCATAAAGATATTGG) and as reverse primer for NoOpiF, we initially used BR2 (TCDGGRTGNCCRAARAAAYCA). Due to poor amplification with NoOpiF-BR2, we switched reverse primer to fwhR2n (GTRATWGCHCCDGCTARWACWGG, Vamos et al. 2017), which gives a shorter amplicon. Systematic studies similarly indicate that sequence recovery is strongly affected by

amplicon length (Tournayre et al. 2020). For NoSpi2 (Lafage et al. 2020), we switched to fwhR2n as reverse primer for the same reason.

In vitro testing: The four selected primers, and also NoSpi2, were tested on DNA extracted from a set of known prey and predator specimens, including negative controls, following optimization of PCR protocols (see below). These tests indicated that NoOpiF-fwhR2n had a better coverage on some prey groups compared to the alternative and was therefore chosen for opilionids, and that LCO-NoAranR had less amplification on target predators, including Lycosidae, than the alternative and was therefore chosen for spiders (Table SI-1). However, neither primer pair amplified psyllids and there were some problems with aphids for NoOpiF. When examining downloaded psyllid sequences, we found quite large discrepancies between psyllid and other Hemiptera sequences within COI, causing problems in finding general Hemiptera primers in suitable areas of COI. We therefore decided on adopting a separate strategy for psyllids by identifying group- or species-specific primers and performing targeted PCR for these species (targeting *Cacopsylla mali*, a common apple pest).

Table S1. PCR amplification for all primer pairs when testing against predator and prey DNA (NA=no test due to limited amount of DNA). Target predators are marked with yellow.

In silico evaluation: In order to examine amplification capacity across the whole range of potential prey, we examined the theoretical amplification capacity in silico using PrimerMiner for the two target sequences (Elbrecht and Leese 2017, Elbrecht et al. 2019). In this program, primers are evaluated based on adjacency, position and type mismatches between primer and template sequence, where mismatches close to the 3'-end carries a larger penalty. For this purpose, we downloaded sequences from a large number of potential arthropod families (both prey and target predator families, Table SI-2) from GenBank and used standard parameters in PrimerMiner. For each family, we binned the output penalty scores in four categories (0-50, 50-100, 100-200 and 200-, Table SI-2) where lower values are better. This testing provided further indications of the suitability of the novel primers (NoOpiF and NoAranR) for gut content analysis of opilionids and spiders respectively, with some restrictions. The amplification problem for Psyllids was confirmed for both NoAranR and NoOpiF. Beside this problem, the analysis of NoAranR also suggest potential amplification problems for Braconidae, Nabidae and Formicidae. Amplification problems was somewhat larger for NoOpiF, mainly for groups within Hemiptera and Coleoptera, although with large variability. However, results from this in silico evaluation sometimes contradicted in vitro testing, where amplification was more successful than suggested by the theoretical analysis. On the other hand, theoretical primer evaluation is somewhat biased due to uneven sequencing within groups, and because of reading errors, and should be cautiously interpreted. Some groups may include more than 10,000 sequences in GenBank whereas other groups include only 100 sequences. Another bias is introduced by the choice of penalties in PrimerMiner that likely do not represent the true primer efficiency.

Table S2. Proportion of sequences within a range of penalty scores from in silico testing of primers on prey and predator species. Lower penalty scores imply higher amplification probability. Target predators are marked with yellow.

Laboratory procedures for metabarcoding

Each primer was tagged with six nucleotides at the 5'-end (Binladen et al. 2007) and for each primer pair we used the unique combinations of 8 forward and 8 reverse tags, resulting in 64 unique combinations per primer pair, as the first level of identification for the individual sample after the sequencing.

For all primer pairs, PCR reactions were carried out in 25 µl reaction volumes containing 2 µl of DNA extract and 12.5 µl of PCR Multiplex Master Mix (Qiagen, Germany). The final concentration of each primer was 2 µM in combinations LCO-NoAranR and NoSpi2-fwhR2n, and 0.5 µM for primer pair NoOpiF-fwhR2n. The negative control containing water instead of DNA was included in each set of PCR reactions. Depending on the primer pair, different thermocycler conditions were used. The first step of an initial activation of the enzyme was common: 95 °C for 15 min. For primer pair LCO-NoAranR we used touchdown PCR: first 14 cycles of: 30 sec at 92.5 °C, 30 sec 53 °C* touchdown -0.5 °C /cycle, 60 sec at 72 °C; next 25 cycles of: 30 sec at 92.5 °C, 30 sec at 50 °C, 60 sec at 72 °C. For primer pair NoOpiF/fwhR2n – 38 cycles of: 30 sec at 94 °C, 90 sec at 57 °C, 90 sec at 72 °C. For primer pair NoSpi2/ fwhR2n – 30 cycles of: 30 sec at 94 °C, 90 sec at 48 °C, 90 sec at 72 °C. A final extension for 10 min at 72 °C was common for all primer pairs. Positive amplifications were confirmed by visual inspection of PCR products in 1.5% agarose gel. No products were obtained from negative controls showing very low probability of cross-contamination. From 739 samples amplified with primer pair LCO-NoAranR, 472 resulted in visible band. From 398 samples amplified with primer pair NoOpiF-fwhR2n, 306 resulted in visible band. From 55 samples amplified with primer pair NoSpi2-fwhR2n, 32 resulted in visible band. The lower amplification success for NoAranR was later discovered to be connected to failures with specific primer-tag combinations for NoSpi2-fwhR2n.

We calculated the dsDNA concentration in each sample using the Qubit® dsDNA HS Assay Kit (ThermoFisher Scientific) and pooled samples in approximately equimolar amounts to a total concentration of 40 ng of dsDNA per sample. Each pooled sample was concentrated to 10 µl using the MinElute PCR Purification Kit (Qiagen). In this way we obtained eleven libraries containing from 27 to 60 PCR products amplified with primer pair LCO-NoAranR,

six libraries containing from 44 to 62 PCR products amplified with primer pair NoOpiF-fwhR2n and one library containing 32 PCR products amplified with primer pair NoSpi2-fwhR2n.

As a second level of sample identification, we constructed separate DNA sequencing libraries from each PCR product pool with distinct indexed adapters, using the TruSeq DNA PCR-free library prep kit (Illumina). We modified the suggested protocol to minimize the risk of PCR-chimera formation in step involving DNA polymerases, as follows: we omitted the end-repair step and performed phosphorylation and adenylation of DNA fragments in a separate reaction, in a total volume of 20 μ l containing 10U T4 Polynucleotide Kinase (ThermoFisher) and 1 mM ATP. We used phosphorylated pooled products in index adapter ligation reactions for each library. We carried out ligations in 20 μ l reaction volumes including 14 μ l PCR products from previous reaction, 1 μ l TruSeq index adapter solution (Illumina), 1U T4 DNA Ligase (ThermoFisher Scientific), 1x T4 DNA Ligase Buffer and 5% PEG 4000. The reaction was performed at 22°C for 1 hour, followed by 10 min at 65°C for the inactivation of the enzyme.

Since ligation is not always complete, the latter reaction may result in products bearing adapters at one end, at both ends or with no adapters at all. In order to choose only the products with successfully ligated index adapters at both ends, we visualized the ligation reaction in 2% agarose gel, run at 80mV for ~2 hours. The products were separated in three bands, with the heaviest corresponding to the desired fraction, where index adapters were ligated at both ends of the PCR products. We excised the band from the gel and purified it using the QIAquick Gel Extraction Kit (Qiagen). Finally, we determined the concentration of each library with a high sensitivity DNA assay in an Agilent 2100 BioAnalyzer instrument (Agilent technologies). We normalized and pooled the libraries according to the bioanalyzer traces. DNA libraries were sequenced in two flow cells on Illumina MiSeq v3, PE 2x300, at Science for Life laboratory, Sweden (www.ScilifeLab.se).

Laboratory procedures for diagnostic PCR

For detecting Psyllidae, we developed new primers (detecting *C. mali*, *C. picta*, *Ctenarytaina spatulata*, *Ctenarytaina eucalipti*): CmF (5'- GATTAGTAGACCAAGGAGTTGG-3') and CmR (5'- CTATTGTGTGAAGATTCTTC-3', with an amplicon of about 200bp. PCR reactions were carried out in 20 μ l reaction volumes containing 2 μ l of DNA extract, 1x buffer,

200 μ M dNTPs mix (Qiagen), 0,5 μ M of each primer, 1mM MgCl₂, 0,1%BSA, 0,5U/ μ l HotStar Taq Plus Polymerase (Qiagen). A positive control containing DNA extracted from *C. mali* was included in each set of PCR reactions, as well as a negative control with water instead of DNA. PCR reaction conditions were: initial activation of the enzyme at 95°C for 5 min, followed by 40 cycles of 30sec at 94°C, 30secs at 56°C, 45sec at 72°C; final extension for 10 min at 72°C. PCR products were separated by electrophoresis in 1,5 % agarose gel.

For detecting aphids, we used primers designed for *Dysaphis plantaginea* (Lefebvre et al. 2017): DpF (5'- GTTATCAAATAATTGCACA C -3') and DpR (5'- CAAATAAAATTAATTGCTCCTAG -3') with an amplicon of 105 bp. PCR reactions were carried out in 20 μ l reaction volumes containing 2 μ l of DNA extract, 1xbuffer, 200 μ M dNTPs mix (Qiagen), 0,5 μ M of each primer, 1mM MgCl₂, 0,1%BSA, 0,5U/ μ l HotStar Taq Polymerase (Qiagen). A positive control containing DNA extracted from *D. plantaginea* was included in each set of PCR reactions, as well as a negative control with water instead of DNA. PCR reaction conditions were: initial activation of the enzyme at 95°C for 15 min, followed by 37 cycles of 30sec at 94°C, 30secs at 54°C, 45sec at 72°C; final extension for 10 min at 72°C. PCR products were separated by electrophoresis in 1,5 % agarose gel.

Detailed results from metabarcoding

Sequencing of the data resulted in 544 prey taxa identified in the spider guts (Table S3), from 61 spider species (Table S4). We also found a good correlation between sequence number and number of predation events per prey species (Fig. S1).

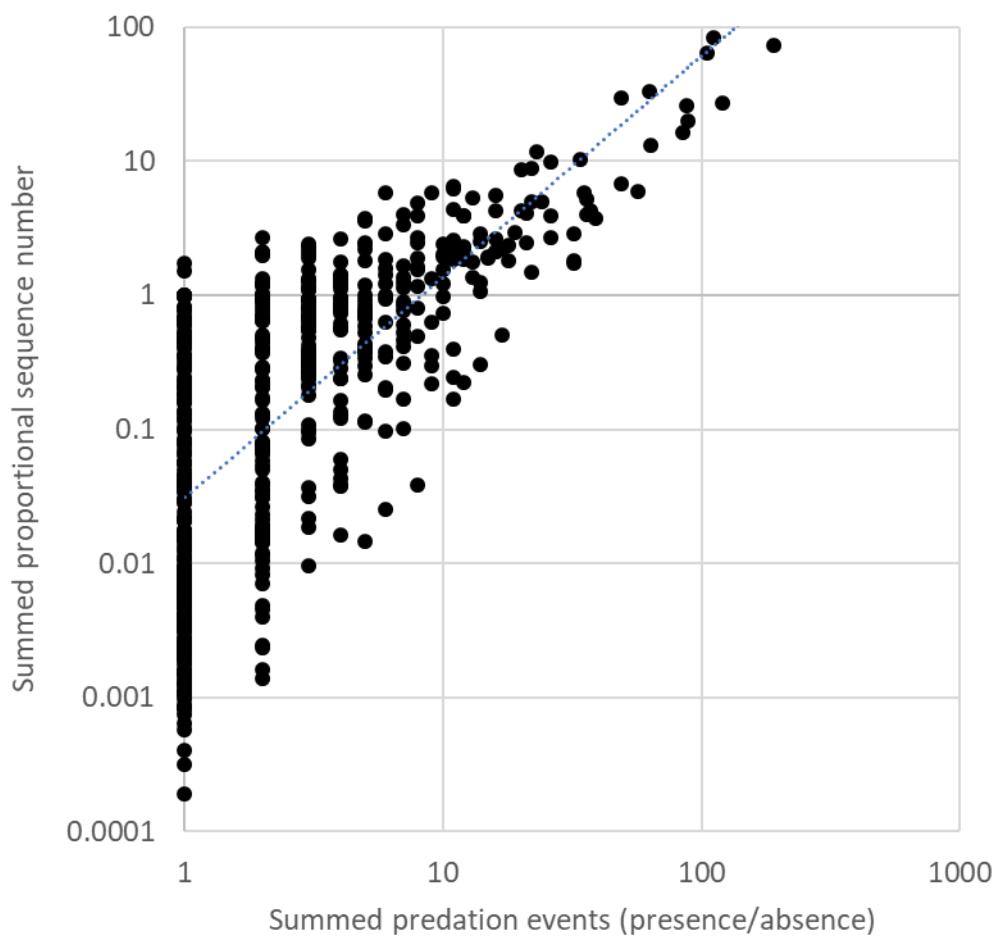

Fig. S1. Relationship between sequence number and number of predation events (presence/absence), summed over all spider individuals, for each prey ($r=0.7$, $N=544$).

Table S3. Total species list with the trophic type and the predation events (PE) and sequence counts for each species in Spanish and Swedish apple orchards.

Order	Family	Prey identity	Trophic type	Spain		Sweden
