# Edge-Bridging and Face-Capping Coordination of Alkenyl Ligands in Triruthenium Carbonyl Cluster Complexes Derived from Hydrazines: Synthetic, Structural, Theoretical, and Kinetic Studies 

Javier A. Cabeza, ${ }^{*[a]}$ Ignacio del Río, ${ }^{[a]}$ José M. Fernández-Colinas, ${ }^{[a]}$ Santiago García-Granda, ${ }^{[b]}$ Lorena Martínez-Méndez, ${ }^{[a]}$ and Enrique Pérez-Carreño ${ }^{[b]}$

#### Abstract

The reactions of the triruthenium cluster complex $\left[\mathrm{Ru}_{3}(\mu-\mathrm{H})\left(\mu_{3}-\eta^{2}-\right.\right.$ $\left.\left.\mathrm{HNNMe}_{2}\right)(\mathrm{CO})_{9}\right] \quad\left(\mathbf{1} ; \mathrm{H}_{2} \mathrm{NNMe}_{2}=1,1-\right.$ dimethylhydrazine) with alkynes

 $\left(\mathrm{PhC} \equiv \mathrm{CPh}, \quad \mathrm{HC} \equiv \mathrm{CH}, \quad \mathrm{MeO}_{2} \mathrm{CC} \equiv\right.$ $\mathrm{CCO}_{2} \mathrm{Me}, \quad \mathrm{PhC} \equiv \mathrm{CH}, \quad \mathrm{MeO}_{2} \mathrm{CC} \equiv \mathrm{CH}$, $\mathrm{HOMe}_{2} \mathrm{CC} \equiv \mathrm{CH}$, 2-pyC $\equiv \mathrm{CH}$ ) give trinuclear complexes containing edgebridging and/or face-capping alkenyl ligands. Whereas the edge-bridged products are closed triangular species (three $\mathrm{Ru}-\mathrm{Ru}$ bonds), the face-capped products are open derivatives (two $\mathrm{Ru}-\mathrm{Ru}$ bonds). For terminal alkynes, products containing gem $\left(\mathrm{RCCH}_{2}\right)$ and/or trans ( RHCCH ) alkenyl ligands have been identified in both edge-bridging and face-capping positions, except for the complex $\quad\left[\mathrm{Ru}_{3}\left(\mu_{3}-\eta^{2}-\mathrm{HNNMe}_{2}\right)\left(\mu_{3}-\eta^{3}-\right.\right.$ $\left.\mathrm{HCCH}-2-\mathrm{py})(\mu-\mathrm{CO})(\mathrm{CO})_{7}\right]$, which has the two alkenyl H atoms in a cis ar-rangement. Under comparable reaction conditions (1:1 molar ratio, THF at reflux, time required for the consumption of complex 1), some reactions give a single product, but most give mixtures of isomers (not all the possible ones), which were separated. To determine the effect of the hydrazido ligand, the reactions of $\left[\mathrm{Ru}_{3}(\mu-\mathrm{H})\left(\mu_{3}-\eta^{2}-\mathrm{MeNNHMe}\right)(\mathrm{CO})_{9}\right] \quad(\mathbf{2}$; HMeNNHMe = 1,2-dimethylhydrazine) with $\mathrm{PhC} \equiv \mathrm{CPh}, \mathrm{PhC} \equiv \mathrm{CH}$, and $\mathrm{HC} \equiv \mathrm{CH}$ were also studied. For edge-bridged alkenyl complexes, the $\mathrm{Ru}-\mathrm{Ru}$ edge that is spanned by the alkenyl ligand depends on the position of the methyl

Keywords: alkenyl ligands alkynes - cluster compounds N ligands $\cdot$ ruthenium
groups on the hydrazido ligand. For face-capped alkenyl complexes, the relative orientation of the hydrazido and alkenyl ligands also depends on the position of the methyl groups on the hydrazido ligand. A kinetic analysis of the reaction of $\mathbf{1}$ with $\mathrm{PhC} \equiv \mathrm{CPh}$ revealed that the reaction follows an associative mechanism, which implies that incorporation of the alkyne in the cluster is rate-limiting and precedes the release of a CO ligand. X-ray diffraction, IR and NMR spectroscopy, and calculations of minimum-energy structures by DFT methods were used to characterize the products. A comparison of the absolute energies of isomeric compounds (obtained by DFT calculations) helped rationalize the experimental results.

## Introduction

Alkenyl groups are important ligands in organometallic chemistry because they are related to many metal-mediated transformations of alkynes and alkenes. However, to date,

[^0]only a few triruthenium carbonyl cluster complexes containing alkenyl ligands are known, ${ }^{[1-4]}$ despite the fact that some of these clusters have been recognized as intermediates or as catalyst precursors for alkyne-alkene codimerization ${ }^{[5]}$ and alkyne hydrogenation, ${ }^{[6]}$ dimerization, ${ }^{[26]}$ polymerization, ${ }^{[2 b]}$ and hydroformylation ${ }^{[2 c]}$ processes.

Most of these alkenyl complexes were prepared by treating hydrido carbonyl cluster complexes with alkynes (by insertion of the alkyne into the $\mathrm{M}-\mathrm{H}$ bond). When the starting hydrido carbonyl cluster complexes contain a bridging ancillary ligand (this is the most common situation), the shape of this ligand may result in the existence of symme-try-unrelated metal-metal edges, and when these clusters react with alkynes, different isomeric edge-bridged alkenyl derivatives may be formed as a result of the attachment of the alkenyl ligand to metal atoms of different $\mathrm{M}-\mathrm{M}$ edges. Generally, these reactions are regioselective and only one of
the possible alkenyl derivatives is formed, but the factors that govern this regioselectivity have not been studied. In this context, while studying the reactivity of diphenylacetylene with hydrido triruthenium clusters that contain facecapping 2-aminopyridine-derived ligands, namely, $\left[\mathrm{Ru}_{3}(\mu-\mathrm{H})\right.$ -$\left.\left(\mu_{3}-\eta^{2}-\mathrm{RNpy}\right)(\mathrm{CO})_{9}\right]$ (where HRNpy represents a 2 -aminopyridine with R on the amino N atom), ${ }^{[14,2]}$ we observed that only derivatives with edge-bridging alkenyl ligands have been reported and that the nature of the R group of the ancillary ligand directs the coordination of the alkenyl ligand to the Ru atoms of a particular edge of the metal triangle. Thus, for $\mathrm{R}=\mathrm{H}$, both the alkenyl and the amido groups span the same $R u-R u$ edge, ${ }^{[1 f]}$ whereas for $R \neq H$, these groups span different $\mathrm{Ru}-\mathrm{Ru}$ edges ${ }^{[2]}$ (e.g., the reactions shown in Scheme 1).

About a decade ago, Süss-Fink et al. reported the synthesis of hydrido triruthenium carbonyl cluster complexes con-

Scheme 1. Reactivity of 2-aminopyridine-derived hydrido triruthenium clusters with alkynes.

(B)
$\left[R u_{3}\left(\mu_{3}-\eta^{2}-R^{1} N N R^{2} \mathrm{Me}\right)\left(\mu_{3}-\mathrm{PhCCHR}{ }^{3}\right)(\mathrm{CO})_{9}\right]$
(C)

Scheme 2. Reactivity of phenyl- and diphenylacetylene with hydrazinederived hydrido triruthenium clusters (as reported by Hansert and Vahrenkamp).
taining face-capping ligands derived from hydrazines, ${ }^{[7]}$ $\left[\mathrm{Ru}_{3}(\mu-\mathrm{H})\left(\mu_{3}-\eta^{2}-\mathrm{R}^{1} \mathrm{NNR}^{2} \mathrm{Me}\right)(\mathrm{CO})_{9}\right]$ (Scheme 2), and Hansert and Vahrenkamp studied their reactions with phenyland diphenylacetylene. ${ }^{[4]}$ The latter reported a similar behavior for both alkynes, each reaction giving a mixture of three trinuclear alkenyl products (Scheme 2): a closed octacarbonyl complex in which the alkenyl group and the amido fragment of the hydrazido ligand span different $\mathrm{Ru}-\mathrm{Ru}$ edges (A), an open octacarbonyl complex having a face-capping alkenyl ligand ( $\mathbf{B}$ ), and a poorly characterized nonacarbonyl derivative (C). Changes in the nature of the groups attached to the hydrazine-derived fragment (cluster compounds derived from methylhydrazine, 1,1-dimethylhydrazine, and 1,2-dimethylhydrazine were used) affected the ratio of the product mixtures, but not to the extent of precluding formation of any of the three products. ${ }^{[4]}$

We found the results of Hansert and Vahrenkamp intriguing for several reasons. 1) For the edge-bridged compounds $\mathbf{A}$, the edge spanned by the alkenyl group is always different from that spanned by the amido fragment, regardless of the nature of the $\mathrm{R}^{1}$ group. However, this contrasts with our observation that, for 2-aminopyridine-derived clusters, different R groups attached to the N atom of the amido fragment direct the alkenyl ligand to different edges of the metal triangle (Scheme 1). 2) The alkenyl ligands of all the products derived from phenylacetylene have their H atoms in gem positions, which implies that only a Markovnikov-type insertion process takes place. However, trans-alkenyl ligands are also known in carbonyl cluster chemistry. ${ }^{[8]}$ 3) Trimetallic clusters bearing face-capping alkenyl ligands are very rare, not only for ruthenium, but also for other metals. This type of coordination has been found in $\left[\mathrm{Os}_{3}(\mu-\mathrm{H})\left(\mu_{3}-\eta^{2}-\right.\right.$ $\left.\left.\mathrm{CF}_{3} \mathrm{CCHCF}_{3}\right)(\mathrm{CO})_{10}\right],\left[{ }^{[9]} \quad\left[\mathrm{WRu}{ }_{2}(\mu-\mathrm{NPh})\left(\mu_{3}-\eta^{2}-\right.\right.\right.$ $\left.\left.\mathrm{CF}_{3} \mathrm{CCHCF}_{3}\right)\left(\eta^{5}-\mathrm{C}_{5} \mathrm{Me}_{5}\right)(\mathrm{CO})_{7}\right],{ }^{[10]}\left[\mathrm{Ru}_{3}\left\{\mu_{3}-\mathrm{NS}(\mathrm{O}) \mathrm{MePh}\right\}\left(\mu_{3}-\right.\right.$ $\eta^{2}$ - RCCHR$\left.)(\mu-\mathrm{CO})(\mathrm{CO})_{7}\right],{ }^{[33]}$ and compounds B. 4) According to the EAN rules, saturated trinuclear compounds with two $\mathrm{M}-\mathrm{M}$ bonds should be 50 -electron species. ${ }^{[11]}$ However, compounds $\mathbf{B}$ are open (two $\mathrm{Ru}-\mathrm{Ru}$ bonds) 48-electron species.

To shed some light on the questions arising from the aforementioned observations, and being aware of the importance of alkenyl ligands in organometallic chemistry, we decided to reinvestigate the reactivity of alkynes with the SüssFink hydrido triruthenium carbonyl clusters derived from hydrazines. We initially studied the reactions of $\left[\mathrm{Ru}_{3}(\mu-\right.$ $\left.\mathrm{H})\left(\mu_{3}-\eta^{2}-\mathrm{HNNMe}_{2}\right)(\mathrm{CO})_{9}\right] \quad$ (1) and $\quad\left[\mathrm{Ru}_{3}(\mu-\mathrm{H})\left(\mu_{3}-\eta^{2}-\right.\right.$ $\left.\mathrm{MeNNHMe})(\mathrm{CO})_{9}\right]$ (2) with phenyl- and diphenylacetylene, and while attempting to rationalize the obtained results, which differ considerably from those reported by Hansert and Vahrenkamp, ${ }^{[4]}$ we carried out a deeper study that involved the use of other alkynes. X-ray diffraction, IR and NMR spectroscopy, and calculations of minimum-energy structures by DFT methods were used to characterize the products. A comparison of the absolute energies of isomeric compounds (obtained by DFT calculations) helped rationalize the experimental results. A kinetic analysis of the reaction of $\mathbf{1}$ with diphenylacetylene is also reported. It sheds some light on the mechanism of these reactions.

## Results and Discussion

Reactivity studies: All reactions were carried out in a systematic way with THF as solvent and a 1:1.1 cluster-to-alkyne ratio, except for the reactions with acetylene, which were carried out by bubbling the alkyne through the solution of the corresponding complex. The reaction solutions were stirred at reflux temperature until the complete disappearance of the starting complex ( $\mathbf{1}$ or $\mathbf{2}$ ) was observed by IR spectroscopy and/or spot TLC. All isolated products are collected in Schemes 3 and 4. The results are summarized in Table 1,

in which the reactions are arranged by alphabetical order of the alkyne used with each starting complex (as in the Experimental Section). Except for the reactions of $\mathbf{1}$ with acetylene and diphenylacetylene, which gave single products, the remaining reactions gave mixtures of several isomers that were separated by chromatographic methods (mostly TLC). Very weak chromatographic bands were not worked up.

To confirm or reject the possibility that some isomeric products could be intermediates in the formation of other isomers, some representative reactions were carried out. Compounds 5, 10, and $\mathbf{1 1}$ (all arising from the reaction of $\mathbf{1}$ with methyl propiolate in refluxing THF, 30 min ) were individually heated in refluxing THF. While compounds 5 and 11 remained unaltered, complete transformation of the $\mu_{3}-$ gem isomer $\mathbf{1 0}$ into the $\mu_{3}$-trans isomer $\mathbf{1 1}$ was observed after 2 h . However, this long reaction time contrasts with the short reaction time ( 30 min ) required for the reaction of 1 with methyl propiolate, which also gives a considerable amount of 11.

Similarly, heating a 3:1 mixture of the $\mu_{3}$-gem and $\mu_{3}$-trans isomers 9 and $\mathbf{1 3}$ (i.e., the crude reaction mixture obtained from 1 and phenylacetylene in THF, reflux, 20 min ) in toluene at reflux temperature for 10 min , allowed the preparation of pure complex 13. The latter transformation took 2 h when it was carried out in refluxing THF.

As the trans products are formed together with the gem products in the reactions of $\mathbf{1}$ with the appropriate terminal alkynes after short reaction times (and/or at low temperatures) and the observed gem to trans isomerization processes require longer reaction times (and/or higher temperatures), the trans products observed in the reactions of $\mathbf{1}$ with some terminal alkynes should not arise, at least to a great extent, from the gem products (by an isomerization process which has a considerable kinetic barrier). On the contrary, it is reasonable to propose that both the gem and trans isomers formed from 1 after short reaction times arise from a common early intermediate that evolves through different pathways (Markovnikov and anti-Markovnikov insertion of the alkyne into the $\mathrm{Ru}-\mathrm{H}$ bond) to give the observed products.

X-ray diffraction studies: The structures of $\mathbf{3}, \mathbf{5}, \mathbf{1 0}, \mathbf{1 1}, \mathbf{1 2}$, and $\mathbf{1 5}$ were determined by X-ray diffraction. For compari-

[a] X-ray diffraction data. [b] Calculated by DFT methods (structure XV).
son purposes, a common atom numbering scheme was used as far as possible for all structures. Selected interatomic distances are given in Table 2.
The structures of $\mathbf{3}$ and $\mathbf{5}$ (Figure 1) correspond to complexes containing edge-bridging alkenyl ligands derived from reactions of $\mathbf{1}$ with diphenylacetylene ( $\mathbf{3}$ ) and methyl propiolate (5), respectively. The latter is an example of a trans arrangement of two H atoms on an edge-bridging al-
kenyl group. In both cases, these ligands span the same $\mathrm{Ru}-\mathrm{Ru}$ edge as the amido fragment of the hydrazido group and are attached to Ru1 through C3, and to Ru2 through C3 and C4, in an analogous manner to that found previously for other edge-bridging alkenyl ligands. ${ }^{[1-3]}$ Both compounds have eight CO ligands, six of which are terminal, one is bridging (in a somewhat asymmetric fashion, since the $\mathrm{C} 20-\mathrm{Ru} 2$ and $\mathrm{C} 20-\mathrm{Ru} 3$ distances differ by ca. $0.2 \AA$ ), and one is semibridging (the $\mathrm{C} 10-\mathrm{Ru} 1$ distance is ca. $0.6 \AA$ shorter than the $\mathrm{C} 10-\mathrm{Ru} 3$ distance). Both compounds are closed triangular species in which the Ru1-Ru2 edge is $0.05-0.08 \AA$ shorter than the other two edges. The $\mathrm{Ru}-\mathrm{Ru}$ distances, ranging from 2.71 to $2.78 \AA$, confirm the presence of $\mathrm{Ru}-\mathrm{Ru}$ single bonds. ${ }^{[12]}$
The structures of $\mathbf{1 0}$ and $\mathbf{1 1}$ (Figure 2) correspond to complexes containing face-capping alkenyl ligands derived from methyl propiolate and $\mathbf{1}$. The two molecular structures are
a)

b)

Figure 2. X-ray structures of a) $\mathbf{1 0}$ and b) $\mathbf{1 1}$.
nearly identical, except for the arrangement of the substituents of the alkenyl groups. The alkenyl H atoms occupy gem positions in 10, and trans positions in 11. In both cases, the alkenyl ligand is attached to Ru2 through C3 and to Ru1 and Ru3 through C3 and C4, in such a way that the C4-Ru3 distance is about $0.3 \AA$ longer than the others. Both compounds have seven terminal and one bridging CO ligands. They are open triangular species because the lengths of the Ru1-Ru3 edges (3.7672(8) $\AA$ in 10 and 3.7511(4) $\AA$ in 11) are outside the bonding range for $\mathrm{Ru}-\mathrm{Ru}$ bonds. ${ }^{[12]}$ The remaining $\mathrm{Ru}-\mathrm{Ru}$ distances are in the range 2.77-2.79 $\AA$.
The molecular structure of $\mathbf{1 2}$ is shown in Figure 3. This complex, which is derived from the reaction of $\mathbf{1}$ with 2ethynylpyridine, contains a face-capping alkenyl ligand with

Figure 3. X-ray structure of $\mathbf{1 2}$.
the H atoms in mutual cis positions. Such an arrangement must be a consequence of the coordination of the pyridyl N atom to Ru3, which also provokes a lengthening of the C4Ru3 distance to $2.65(1) \AA$. All remaining structural features of this compound are comparable with those of $\mathbf{1 0}$ and $\mathbf{1 1}$.
The structure of $\mathbf{1 5}$ (Figure 4) corresponds to an edgebridging alkenyl complex derived from the reaction of 2 with diphenylacetylene. In this case, the alkenyl ligand spans the $\mathrm{Ru}-\mathrm{Ru}$ edge that is close to the hydrogen atom of the 1,2-dimethylhydrazido group and is attached to Ru3 through

C 3 and to Ru1 through C3 and C4. As in the edge-bridged compounds $\mathbf{3}$ and $\mathbf{5}$, the bridging CO ligand that is trans to the alkenyl C3-C4 fragment is slightly asymmetric (C11Ru1 and $\mathrm{C} 11-\mathrm{Ru} 2$ differ by ca. $0.2 \AA$ ), whereas the CO ligand that is trans to the $\sigma$ interaction between the alkenyl ligand and the triruthenium framework, that is, the $\mathrm{C} 3-\mathrm{Ru} 3$ bond, is semibridging (difference between $\mathrm{C} 20-\mathrm{Ru} 3$ and $\mathrm{C} 20-\mathrm{Ru} 2$ is $0.68 \AA$ ). As in $\mathbf{3}$ and $\mathbf{5}$, the amido-bridged edge of the metal triangle, Ru1-Ru2, is slightly shorter (by ca. $0.1 \AA$ ) than the other two.

Hansert and Vahrenkamp ${ }^{[4]}$ reported the X-ray structures of $\mathbf{9}$ and 16. The structure of $\mathbf{9}$ is comparable to that of $\mathbf{1 0}$, except for the R substituent of the alkenyl fragment. In 16 the alkenyl ligand has a gem arrangement of its H atoms and it bridges the $\mathrm{Ru}-\mathrm{Ru}$ edge adjacent to the NH fragment of the 1,2-dimethylhydrazido ligand, as in $\mathbf{1 5}$.

Intriguingly, despite being 48 -electron species, the facecapped alkenyl complexes have only two metal-metal bonds and thus disobey the EAN rules. As noted above, trimetallic clusters bearing face-capping alkenyl ligands are very rare. While $\left[\mathrm{Os}_{3}(\mu-\mathrm{H})\left(\mu_{3}-\eta^{2}-\mathrm{CF}_{3} \mathrm{CCHCF}_{3}\right)(\mathrm{CO})_{10}\right]^{[9]}$ and $\left[\mathrm{WRu}_{2}(\mu-\right.$ $\left.\mathrm{NPh})\left(\mu_{3}-\eta^{2}-\mathrm{CF}_{3} \mathrm{CCHCF}_{3}\right)\left(\eta^{5}-\mathrm{C}_{5} \mathrm{Me}_{5}\right)(\mathrm{CO})_{7}\right]^{[10]}$ are closed $48-$ electron triangular clusters, Süss-Fink's complexes $\left[\mathrm{Ru}_{3}\left\{\mu_{3}-\right.\right.$ $\left.\mathrm{NS}(\mathrm{O}) \mathrm{MePh}\}\left(\mu_{3}-\eta^{2}-\mathrm{RCCHR}\right)(\mu-\mathrm{CO})(\mathrm{CO})_{7}\right]^{[3 a]}$ are open (two $\mathrm{Ru}-\mathrm{Ru}$ bonds) 48-electron triangular clusters.

The alkenyl C3-C4 distances of the face-capped complexes are similar to those of the edge-bridged clusters. This implies that the bond order of the alkenyl $\mathrm{C}-\mathrm{C}$ bond is similar for both types of complexes. This supports the proposal that the alkenyl ligands behave as three-electron donors in both edge-bridging and face-capping coordination modes. Therefore, all the alkenyl clusters reported in this article are 48 -electron species.

IR spectroscopy: Three types of absorption patterns were observed in the carbonyl bond-stretching region of the IR spectra of all these alkenyl complexes (Figure 5). This led us to classify the compounds into three groups (Tables 3-5). Once the structures of one or several members of each group were ascertained by other structural techniques (e.g., NMR spectroscopy, X-ray diffraction, or minimum-energy

Figure 4. X-ray structure of $\mathbf{1 5}$.

Figure 5. IR spectra of a) $\mathbf{1 5}$, b) $\mathbf{9}$, and c) $\mathbf{1 3}$ in the $v_{\mathrm{CO}}$ region, as representative examples of the band patterns observed for compounds having an edge-bridging alkenyl ligand (left), a face-capping alkenyl ligand and one bridging CO ligand (center), and a face-capping alkenyl ligand and two bridging CO ligands (right).

Table 3. IR data for the compounds having edge-bridging alkenyl ligands.

DFT calculations), the three groups were identified as being composed of 1) complexes having an edge-bridging alkenyl ligand (Table 3, left spectrum of Figure 5), 2) complexes having a face-capping alkenyl and one bridging CO ligand (Table 4, central spectrum of Figure 5), and 3) complexes
having a face-capping alkenyl and two bridging CO ligands (Table 5, right spectrum of Figure 5). Within each group, changes in the nature of the alkenyl ligand substituents affect the position (wavenumber) of the $v_{\mathrm{CO}}$ bands, but they do not significantly alter the relative intensity (transmittance) of the absorptions (the band pattern is maintained). Curiously, all isolated compounds having an edge-bridging alkenyl ligand show the same pattern of $v_{\mathrm{CO}}$ absorptions, regardless of the edge that is spanned by the alkenyl ligand with respect to the face-capping hydrazido fragment. In addition, the $v_{\mathrm{CO}}$ absorptions are also nearly unaffected by the position of the methyl groups on the hydrazido fragment and by the gem, cis, or trans stereochemistry of the alkenyl ligand (maintaining the nature of the substituents).

NMR spectroscopy: Table 6 collects the ${ }^{1} \mathrm{H}$ NMR data of $\mathbf{3}-$ 23. All products contain at least one hydrogen atom on the alkenyl ligand, that is, that arising from the original hydrido ligand of starting complex $\mathbf{1}$ or $\mathbf{2}$. The resonance of this proton, which is always $c i$ to the Ru atom that is $\sigma$-bonded to the alkenyl ligand (except in 12), is observed in the range $\delta=2.1-4.5 \mathrm{ppm}$. An additional resonance is observed for alkenyl ligands derived from terminal alkynes (excluding acetylene), whose chemical shift and coupling constant depend upon the stereochemistry of the alkenyl ligand. Thus, for gem-alkenyls ( H atoms in gem positions, i.e., 4, 6, 9, 10, 16, 19, and 21), this resonance always appears at a lower chemical shift (in the range $\delta=2.8-1.7 \mathrm{ppm}$ ), with a small coupling constant ( $J$ in the range $5.6-2.5 \mathrm{~Hz}$ ), whereas for trans-alkenyls ( H atoms in trans arrangement, i.e., 5, 11, 13, and 14), it is observed at a high chemical shift (in the range $\delta=$ $10.9-6.4 \mathrm{ppm}$ ) with a larger coupling constant ( $J$ in the range $14.8-11.9 \mathrm{~Hz}$ ). The spectrum of $\mathbf{1 2}$, the only complex having a cis arrangement of the two hydrogen atoms on the alkenyl ligand, shows two doublets for these protons at $\delta=$ 7.16 and 5.63 ppm , with $J=7.9 \mathrm{~Hz}$. The three coupling types (gem, trans, and cis) are observed in the spectra of the products derived from acetylene ( $\mathbf{7}, \mathbf{1 7}, \mathbf{2 0}$, and 22).

Simple ${ }^{1} \mathrm{H}$ NMR spectroscopy was useful for assigning the stereochemistry of the alkenyl ligands in the complexes, but it gave no hint to how the alkenyl ligands are attached to the hydrazido-trimetal framework. Such information was obtained from difference ${ }^{1} \mathrm{H}$ NOE NMR spectra, which helped determine the relative positions of the hydrazido and alkenyl ligands on the clusters. Only two representative examples are presented and discussed here. Difference ${ }^{1} \mathrm{H}$ NOE NMR spectra for $\mathbf{4}, \mathbf{7}, \mathbf{1 5}, \mathbf{1 6}, \mathbf{1 7}, \mathbf{1 9}, \mathbf{2 0}, \mathbf{2 2}$, and $\mathbf{2 3}$ are available as Supporting Information.

Figure 6 shows the ${ }^{1} \mathrm{H}$ NMR spectra of $\mathbf{1 8}$ (for which IR spectroscopy confirmed the presence of an edge-bridging alkenyl ligand) and the NOE enhancements produced after presaturation at the frequencies of some of its signals. Interestingly, presaturation of the alkenyl CH resonance produced a positive enhancement of the methyl resonance of the bridgehead NMe fragment (trace b) and vice versa (trace d), as expected for protons that are close to each other. ${ }^{[13]}$ Presaturation of the doublet corresponding to the methyl protons of the MeNH group (trace e) or of the quartet of the NH proton (trace c) produced no enhancement of

Table 6. ${ }^{1} \mathrm{H}$ NMR data of compounds 3-23.

the alkenyl CH resonance; this confirms that the alkenyl ligand is remote from all H atoms of the MeNH group. The analogous situation observed in the spectra of $\mathbf{1 9}$ and $\mathbf{2 0}$ (Supporting Information) confirms that they have a similar arrangement of ligands. However, for 15-17, the structures of which have been determined by X-ray diffraction, a positive NOE is observed between the alkenyl CH and the NH resonances (presaturation of one enhances the other), but not between the resonances of any of the methyl groups and the alkenyl CH group (Supporting Information). These data strongly support the structures proposed for these complexes in Scheme 4.
Figure 7 shows the ${ }^{1} \mathrm{H}$ NMR spectrum of compound $\mathbf{2 1}$ (for which IR spectroscopy confirmed that it has a face-capping alkenyl ligand) and the NOE enhancements produced after presaturation at the frequencies of some of its signals. Traces (e) and (f) are of particular interest because they unequivocally indicate that the open $\mathrm{Ru}-\mathrm{Ru}$ edge of the clus-
ter is adjacent to the methyl group of the MeNH moiety. As expected for such a structure, presaturation of the MeNH methyl resonance enhanced one of the alkenyl CH resonances (trace e) and vice versa (trace f). The analogous situation observed in the spectra of $\mathbf{2 2}$ and $\mathbf{2 3}$ (Supporting Information), confirms that they have a similar ligand arrangement.

Theoretical calculations: Minimum-energy structure calculations were carried out by using DFT methods. Calculations were performed on selected real molecules (products that were isolated in the present work) and on hypothetical ones with the aim of not only comparing the thermodynamic stabilities of real and hypothetical isomeric compounds (important for rationalizing the experimental results), but also to assign or confirm the structures of compounds for which no X-ray diffraction data were available. No simplified model compounds were used for the calculations.

Figure $6 .{ }^{1} \mathrm{H}$ NMR spectrum $\left(\mathrm{CD}_{2} \mathrm{Cl}_{2}, 20^{\circ} \mathrm{C}, 400 \mathrm{MHz}\right)$ of $\mathbf{1 8}$ (a) and difference ${ }^{1} \mathrm{H}$ NOE NMR spectra after presaturation at the frequencies of the CH (b), MeNH (c), NMe (d), and $M e \mathrm{NH}$ (e) resonances. The peak marked with an asterisk is due to residual $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solvent.

Calculated structures are assigned Roman numbers, irrespectively of whether they correspond to real (designated by Arabic numbers) or hypothetical compounds. Computergenerated images of all these structures and lists of atomic coordinates are given as Supporting Information.

For the cases in which both experimental (X-ray diffraction) and theoretical (DFT calculations) structural data were obtained, the bond lengths and angles given by both methods are practically identical. This fact validates the calculations.

Scheme 5 shows the calculated energies of structures belonging to two families of isomeric compounds, formally derived from reactions of diphenylacetylene and acetylene with 1. For both alkynes, structure I, which corresponds to species in which the amido and alkenyl fragments span the same $\mathrm{Ru}-\mathrm{Ru}$ edge, is much more stable (by $>10 \mathrm{kcalmol}^{-1}$ )

Figure 7. ${ }^{1} \mathrm{H}$ NMR spectrum $\left(\mathrm{CD}_{2} \mathrm{Cl}_{2}, 20^{\circ} \mathrm{C}, 400 \mathrm{MHz}\right)$ of $\mathbf{2 1}$ (a) and difference ${ }^{1} \mathrm{H}$ NOE NMR spectra after presaturation at the frequencies of the MeNH (b), HCH (c), $\mathrm{N} M e$ (d), $M e \mathrm{NH}$ (e), and $H C H$ (f) resonances. The peak marked with an asterisk is due to residual $\mathrm{CH}_{2} \mathrm{Cl}_{2}$ solvent.
than structure II, which corresponds to species in which the amido and alkenyl fragments span different $\mathrm{Ru}-\mathrm{Ru}$ edges. This explains why all the isolated products derived from 1 that contain an edge-bridging alkenyl ligand have the ligand arrangement of structure $\mathbf{I}$. For face-capping derivatives of both alkynes, asymmetric structure III is much more stable than symmetric IV. This supports the fact that no symmetric compounds containing face-capping alkenyl ligands have been experimentally obtained. Whereas the acetylene-derived structures Ib and IIIb have similar energies (they only differ by $0.68 \mathrm{kcalmol}^{-1}$ ), the diphenyl derivative $\mathbf{I a}$ is $3.84 \mathrm{kcalmol}^{-1}$ more stable than IIIa. Therefore, different alkynes may result in minimum-energy products with different isomeric structures. In fact, compounds $\mathbf{3}$ and $\mathbf{7}$, which are the only products of the reactions of $\mathbf{1}$ with diphenylacetylene and acetylene, respectively, have different structures.

When terminal alkynes are used, their alkenyl products can have a gem or a trans arrangement of their two H atoms. Scheme 6 shows the relative energies of DFT-optimized structures of four isomeric products derived from methyl propiolate and $\mathbf{1}$ (structures analogous to II and IV were not calculated because they were expected to be less stable; see above). These energies clearly indicate

Scheme 5. Relative energies [ $\mathrm{kcalmol}^{-1}$ ] of DFT-calculated minimum-energy structures of isomeric products formally derived from reactions of diphenylacetylene and acetylene with $\mathbf{1}$. The energy of the most stable structure of each family of isomers is assigned as $0.00 \mathrm{kcal} \mathrm{mol}^{-1}$.

Scheme 6. Relative energies $\left[\mathrm{kcalmol}^{-1}\right]$ of DFT-optimized structures of isomeric products formally derived from methyl propiolate and $\mathbf{1}$. The energy of the most stable structure is assigned as $0.00 \mathrm{kcalmol}^{-1}$.
that trans-alkenyl products are thermodynamically more stable than gem-alkenyl derivatives, both for edge-bridging and face-capping situations.
The asymmetry of the bridging hydrazido ligand of compound $\mathbf{2}$ increases the number of possible isomeric alkenyl derivatives. Scheme 7 shows the calculated minimum-energy structures of edge-bridging and face-capping isomers formal-

Scheme 7. Relative energies [ $\mathrm{kcalmol}^{-1}$ ] of DFT-optimized structures of isomeric products formally derived from reactions of phenylacetylene and acetylene with $\mathbf{2}$. The energy of the most stable structure of each family of isomers is assigned as $0.00 \mathrm{kcalmol}^{-1}$.
ly derived from reactions of phenylacetylene and acetylene with 2. For both alkynes, structures IX, XI, and XIV are the most stable and correspond to the three isomeric products experimentally obtained from the reactions of $\mathbf{2}$ with phenylacetylene ( $\mathbf{1 6}, \mathbf{1 9}$, and 21) and acetylene (17, 20, and 22). The energies of the phenylacetylene-derived structures IXa, XIa, and XIVa are very close to each other (the least stable, IXa, is only $0.51 \mathrm{kcalmol}^{-1}$ above the most stable, XIa). However, for the acetylene-derived compounds, structure XIb is $2.89 \mathrm{kcalmol}^{-1}$ less stable than XIVb. Therefore, changes in the R substituents of the alkenyl fragments may induce important changes in the relative stability of their isomeric products.
From these calculations, it can be concluded that, for edge-bridged alkenyl derivatives, the least stable structures

Table 2. This structure is the output of a calculation for which the input was the optimized structure of $\mathbf{1 1}$ (VII), which contains only one bridging CO ligand, appropriately modified by substituting a phenyl group for the original $\mathrm{CO}_{2} \mathrm{Me}$ group. Overall, the calculated structure of $\mathbf{1 3}$ is very similar to that of 11, the major differences between them being that the Ru1-Ru3 and C4-Ru1 distances are 0.14 and $0.22 \AA$, respectively, longer in $\mathbf{1 3}$ than in $\mathbf{1 1}$, and that the C11O11 carbonyl ligand asymmetrically spans the Ru1-Ru2 edge of $\mathbf{1 3}$ (C11-Ru1 2.018, C11-Ru2 $2.249 \AA$ ), whereas it is terminal in 11. Therefore, within the family of facecapped alkenyl complexes, noticeable structural changes in the attachment of the CO ligands to the metal atoms can be provoked by subtle changes in the nature of the alkenyl ligands, such as the gem to trans arrangement of the alkenyl

Figure 8. DFT-optimized molecular structure of $\mathbf{1 3}$ (structure XV).
hydrogen atoms, for example, 9 (gem, one bridging CO ligand) and $\mathbf{1 3}$ (trans, two bridging CO ligands), or different R substituents on the alkenyl fragment while maintaining the positions of the hydrogen atoms, for example, $\mathbf{1 1}$ (trans, $\mathrm{R}=\mathrm{CO}_{2} \mathrm{Me}$, one bridging CO ligand) and $\mathbf{1 3}$ (trans, $\mathrm{R}=\mathrm{Ph}$, two bridging CO ligands).

Kinetic studies: To shed light on the mechanistic aspects of these reactions, the kinetics of the reaction of $\mathbf{1}$ with diphenylacetylene were studied as a representative example.

Kinetic data were obtained under pseudo-first-order conditions $\left(\left[\mathrm{Ph}_{2} \mathrm{C}_{2}\right] \gtrdot[\mathbf{1}]\right)$, by measuring the disappearance of the IR absorption at $2081 \mathrm{~cm}^{-1}$ of $\mathbf{1}$ as a function of time (details are given in the Experimental Section). The results indicate that the reaction is first-order in the concentration of trinuclear complex and first-order in alkyne concentration, with a rate law of the type $v=k_{2}\left[\mathrm{Ph}_{2} \mathrm{C}_{2}\right][\mathbf{1}]$. Secondorder rate constants $k_{2}$ and activation parameters $\left(\Delta H^{+}\right.$and $\Delta S^{\ddagger}$ ) are given in Table 7.

Table 7. Second-order rate constants and activation parameters for the reaction of $\mathbf{1}$ with $\mathrm{Ph}_{2} \mathrm{C}_{2}$.

| $T[\mathrm{~K}]$ | $10^{4} k_{2}$ <br> $\left[\mathrm{~s}^{-1} \mathrm{~mol}^{-1} \mathrm{~L}\right]$ | $\Delta H^{+}$ <br> $\left[\mathrm{kcalmol}^{-1}\right]$ | $\Delta S^{\ddagger}$ <br> $\left[\mathrm{cal} \mathrm{K}^{-1} \mathrm{~mol}^{-1}\right]$ |
| :--- | :--- | :---: | :---: |
| 318 | 6.4 | $14 \pm 2$ | $-32 \pm 1$ |
| 328 | 9.6 |  |  |
| 338 | 19.2 |  |  |
| 348 | 49.6 |  |  |

Second-order kinetics, small $\Delta H^{+}$, and negative $\Delta S^{\ddagger}$ are consistent with an associative mechanism. ${ }^{[14]}$ Although a reaction pathway in which the addition of the alkyne is preceded by a pre-equilibrium that involves cleavage of a bond $(\mathrm{Ru}-\mathrm{Ru}$ or $\mathrm{Ru}-\mathrm{N})$ to create a vacant site in the cluster would also follow second-order kinetics, the experimental $\Delta H^{+}$is too low for such a process, for which $\Delta H^{+}$would be sum of the bond energy of the broken bond and the activation barrier for attack of the alkyne on the coordinatively unsaturated metal atom. ${ }^{[15]}$
Only one previous mechanistic study on reactions of trinuclear carbonyl clusters containing face-capping N -donor
ligands has been reported. ${ }^{[15]}$ It deals with reactions of phosphane ligands with anionic complexes of the type [PPN] $\left[\mathrm{Ru}_{3}\left(\mu_{3}-\eta^{2}-\mathrm{Xpy}\right)(\mu-\mathrm{CO})_{3}(\mathrm{CO})_{6}\right](\mathrm{X}=\mathrm{S}, \mathrm{NMe}, \mathrm{NPh})$. These reactions also follow second-order kinetics, and it was proposed that they take place by an associative mechanism in which attack of the phosphane on the metal atom is accompanied by cleavage of an $\mathrm{Ru}-\mathrm{X}$ bond. A subsequent CO loss would reform the $\mathrm{Ru}-\mathrm{X}$ bond and yield the monosubstituted product. ${ }^{[15]}$

Although a mechanism of this type could also be proposed for the first step of the reactions described here, an alternative proposal in which the attack of the entering ligand is concomitant with a lengthening of several bonds of the cluster, and not with cleavage of a localized $\mathrm{Ru}-\mathrm{X}$ bond, would also be possible. ${ }^{[16]}$ Such a proposal is substantiated by a few reports that describe closed, trinuclear, ligandbridged, 50 -electron, carbonyl clusters of ruthenium ${ }^{[17]}$ and osmium ${ }^{[18]}$ in which the three $\mathrm{M}-\mathrm{M}$ distances are longer than expected for normal single bonds but shorter than open $\mathrm{M} \cdots \mathrm{M}$ edges.

Unfortunately, the fact that the rate-limiting step is the first step of the reaction pathway (the remaining steps are faster and occur later) prevented the isolation and/or characterization of reaction intermediates that could shed more light on how the final alkenyl products are formed.

Discrepancies with the results of Hansert and Vahrenkamp:
A comparison of our results and those reported by Hansert and Vahrenkamp ${ }^{[4]}$ (summarized in Scheme 2 and in the Introduction) reveals many discrepancies.

For certain reagents, the number of products obtained by the two groups is different. This may be due to the use of different reaction and/or separation conditions. But it is curious that in no case did they obtain any trans alkenyl product derived from phenylacetylene, as we have done.

The most important discrepancies correspond to structural assignments. Hansert and Vahrenkamp had the problem of having three different products from their reactions, of which one was clearly face-capped (IR) but the other two had very similar IR spectra (as stated above, the IR spectra of all the edge-bridged alkenyl products are very similar in the carbonyl stretching region). They also had the X-ray structure of $\mathbf{1 6}$ (structure $\mathbf{A}$ in Scheme 2). On the basis of these data, they divided their edge-bridged alkenyl products into two groups, one for the products of structure $\mathbf{A}$, and the other for products of unknown structure (compounds $\mathbf{C}$ in Scheme 2, which Hansert and Vahrenkamp said had nine CO ligands). As a consequence of the lack of a clear differentiating criterion to make such a classification, they assigned structure $\mathbf{A}$ to compounds that in fact do not have that structure, for example, $\mathbf{3}, \mathbf{1 8}$, and $\mathbf{1 9}$, in which the alkenyl ligand and the amido fragment span the same edge of the metal triangle, and included complex 15, which has structure $\mathbf{A}$, in group $\mathbf{C}$.

We encountered an additional problem when we tried to elucidate the true structures of the compounds described by Hansert and Vahrenkamp. When comparing IR and NMR data, we found that the data for some of their compounds did not match those of any of our compounds. Furthermore,
they reported the X-ray structure of $\mathbf{1 6}$ but, curiously, the reported spectroscopic data of this compound matched our data for 19. In addition, our data for $\mathbf{1 6}$ matched their data for a compound they tentatively formulated as $\left[\mathrm{Ru}_{3}\left(\mu_{2}-\eta^{2}-\right.\right.$ $\mathrm{MeNNHMe})\left(\mu-\eta^{2}-\mathrm{PhCCH}_{2}\right)(\mathrm{CO})_{9}$ ] and assigned to group $\mathbf{C}$ (Scheme 2). To further clarify the situation, we determined the X-ray structure of the compound with those spectroscopic data, and the structure of $\mathbf{1 6}$ resulted, confirming that our spectroscopic data were correct.

## Conclusion

Very few reactions of alkynes with face-capped hydrido triruthenium clusters had been previously reported. Diphenylacetylene was the most widely used alkyne by us ${ }^{[1]}$ and Lavigne et al. ${ }^{[2]}$ in reactions with clusters derived from 2 -aminopyridines. Curiously, these reactions are regioselective in the sense that they give only one product, an edgebridged alkenyl derivative. Other internal and terminal alkynes were used by Süss-Fink et al. in reactions with $\left[\mathrm{Ru}_{3}-\right.$ $\left.(\mu-\mathrm{H})\left\{\mu_{3}-\mathrm{NS}(\mathrm{O}) \mathrm{MePh}\right\}(\mathrm{CO})_{9}\right]$. They observed mixtures of various isomeric edge-bridged and face-capped alkenyl products, partly as a consequence of the asymmetry of the bridging sulphoximido ligand. ${ }^{[32]}$ In none of these previous studies were the results rationalized in terms of the kinetic and/or thermodynamic stability of the possible isomeric products.
The results reported here represent a rather broad picture of the reactivity of alkynes with hydrazido-bridged hydridotriruthenium carbonyl clusters and complement previous data on the reactivity of alkynes with triruthenium carbonyl clusters containing other face-capping ligands. We have shown that the selectivity of the reactions is influenced by the nature of both the face-capping ligand and the alkyne reagent. Density functional calculations helped us to deduce that the products of the reactions that give a single product (those of $\mathbf{1}$ with diphenylacetylene and acetylene) are the most stable ones among the possible isomeric products (Scheme 5), and that the products of the reactions that give mixtures of isomers have similar thermodynamic stabilities and include the most stable product of the possible isomeric products (Schemes 6 and 7). Therefore, the kinetic aspects of the migratory insertion processes (formation of the alkenyl ligands) have little influence on the selectivity of the reactions. This implies that, at short reaction times and/or at low temperatures, when different alkenyl products are formed, none of them is an intermediate in the formation of any of the others; in other words, they are all formed, through pathways that have similar activation energies, from a common unstable hydrido alkyne intermediate that arises from coordination of the alkyne to $\mathbf{1}$ or $\mathbf{2}$. A kinetic study demonstrated that the formation of this intermediate follows an associative pathway and that this process is the rate-limiting step of the overall reaction. We also showed that gem-alkenyl products can be converted into trans-alkenyl products, but this transformation has a higher activation energy than the formation of the trans or gem products directly from the hydrido alkyne intermediate.

Despite the great deal of information contained in this article on the reactivity of hydrazido-capped hydrido triruthenium carbonyl clusters with alkynes, some questions are still open. Why, among the possible isomeric products of a reaction, is one more stable than the others? Why are the complexes that contain face-capping alkenyl ligands open clusters (two $\mathrm{Ru}-\mathrm{Ru}$ bonds), contrary to the predictions of the EAN rules for trinuclear 48 -electron species? The answers to these questions will require in-depth theoretical calculations that we leave for forthcoming research.

## Experimental Section

General: Solvents were dried over $\mathrm{Na}\left[\mathrm{Ph}_{2} \mathrm{CO}\right]$ (THF, diethyl ether, hydrocarbons), or $\mathrm{CaH}_{2}$ (dichloromethane, 1,2-dichloroethane) and distilled under nitrogen prior to use. The reactions were carried out under nitrogen by using Schlenk/vacuum line techniques and were routinely monitored by solution IR spectroscopy and by spot TLC on silica gel. Compounds 1 and 2 were prepared as described elsewhere. ${ }^{[4,7]}$ IR: PerkinElmer FT Paragon 1000X. NMR: Bruker AV-400 and DPX-300, room temperature, TMS as internal standard $(\delta=0)$. Microanalyses: PerkinElmer 2400. MS: VG Autospec double-focusing mass spectrometer operating in the $\mathrm{FAB}+$ mode; ions were produced with a standard $\mathrm{Cs}^{+}$gun at ca. 30 kV ; 3-nitrobenzyl alcohol (NBA) was used as matrix. All isolated products gave satisfactory C, H, N, microanalyses (Supporting Information). All their FAB + mass spectra showed the corresponding molecular ion (Supporting Information).
The following description of the reactions of compounds $\mathbf{1}$ and $\mathbf{2}$ with alkynes is arranged in alphabetical order of the alkyne name.
Reaction of 1 with acetylene: synthesis of $\left[\mathrm{Ru}_{3}\left(\mu_{3}-\eta^{2}-\mathrm{HNNMe}_{2}\right)\left(\mu_{3}-\eta^{2}-\right.\right.$ $\left.\left.\mathbf{H C C H}_{2}\right)(\mu-\mathbf{C O})(\mathbf{C O})_{7}\right]$ (7): Acetylene was gently bubbled through a solution of $\mathbf{1}(50 \mathrm{mg}, 0.081 \mathrm{mmol})$ in THF $(30 \mathrm{~mL})$ at reflux for 20 min . The color changed from yellow to orange. The solvent was removed under reduced pressure and the residue was crystallized from dichloromethane/ hexane to give $\mathbf{7}$ as an brownish orange solid ( $44 \mathrm{mg}, 89 \%$ ).
Reaction of 1 with dimethyl acetylenedicarboxylate: synthesis of $\left[\mathbf{R u}_{3}\left(\mu_{3^{-}}\right.\right.$ $\left.\left.\boldsymbol{\eta}^{2}-\mathrm{HNNMe}_{2}\right)\left(\mu_{3}-\boldsymbol{\eta}^{2}-\mathrm{MeO}_{2} \mathrm{CCCHCO}_{2} \mathrm{Me}\right)(\boldsymbol{\mu}-\mathrm{CO})(\mathrm{CO})_{7}\right](8)$ : A solution of $1(50 \mathrm{mg}, 0.081 \mathrm{mmol})$ and dimethyl acetylenedicarboxylate $(10 \mu \mathrm{~L}$, 0.089 mmol ) in THF ( 20 mL ) was stirred under reflux for 20 min . The color changed from yellow to dark orange. The solvent was removed under reduced pressure and the residue was separated by TLC (silica gel) with hexane/THF (4/1) as eluant. Extraction of the major band (third, orange) allowed the isolation of $\mathbf{8}$ as an orange solid ( 28 mg , $47 \%$ ).
Reaction of 1 with diphenylacetylene: synthesis of $\left[\operatorname{Ru}_{3}\left(\mu_{3}-\eta^{2}-\right.\right.$ $\left.\left.\mathbf{H N N M e}_{2}\right)\left(\boldsymbol{\mu}-\boldsymbol{\eta}^{2}-\mathbf{P h C C H P h}\right)(\boldsymbol{\mu}-\mathbf{C O})_{2}(\mathbf{C O})_{6}\right]$ (3): A solution of $\mathbf{1}(50 \mathrm{mg}$, $0.081 \mathrm{mmol})$ and diphenylacetylene ( $17 \mathrm{mg}, 0.089 \mathrm{mmol}$ ) in THF ( 30 mL ) was stirred under reflux for 85 min . The color changed from yellow to red. The solvent was removed under reduced pressure and the residue was crystallized from dichloromethane/hexane to give $\mathbf{3}$ as a red solid ( $49 \mathrm{mg}, 79 \%$ ).
Reaction of 1 with 2-ethynylpyridine: synthesis of $\left[R u_{3}\left(\mu_{3}-\eta^{2}-\right.\right.$ $\left.\left.\mathrm{HNNMe}_{2}\right)\left(\mu-\eta^{2}-\mathrm{pyCCH}_{2}\right)(\mu-\mathrm{CO})_{2}(\mathbf{C O})_{6}\right]$ (6) and $\left[\mathrm{Ru}_{3}\left(\mu_{3}-\eta^{2}\right.\right.$ $\left.\left.\mathbf{H N N M e}_{2}\right)\left(\mu_{3}-\boldsymbol{\eta}^{3}-\mathbf{H C C H p y}\right)(\boldsymbol{\mu}-\mathbf{C O})(\mathbf{C O})_{7}\right](\mathbf{1 2 )}$ : A solution of $\mathbf{1}(100 \mathrm{mg}$, 0.162 mmol ) and 2-ethynylpyridine ( $18 \mu \mathrm{~L}, 0.178 \mathrm{mmol}$ ) in THF ( 40 mL ) was stirred under reflux for 12 min . The color changed from yellow to orange. The solvent was removed under reduced pressure, the residue was dissolved in dichloromethane ( 2 mL ), and the resulting solution was supported on a silica gel chromatographic column $(3 \times 20 \mathrm{~cm})$ packed in hexane. Hexane/dichloromethane (1/1) eluted four bands. The first three were very weak and were not collected. The fourth band contained 12, which was isolated as a red solid after solvent removal ( $13 \mathrm{mg}, 12 \%$ ). Further elution of the column with dichloromethane afforded an orange band, which contained a mixture of compounds. This mixture was separated by TLC (silica gel). Repeated elution with hexane/dichloromethane
(1/1) allowed the separation of the major band, which, after workup, afforded 6 as an orange solid ( $19 \mathrm{mg}, 17 \%$ ).
Reaction of 1 with 2 -methylbut-3-yn-2-ol: synthesis of $\left[\operatorname{Ru}_{3}\left(\mu_{3}-\eta^{2}-\right.\right.$ $\left.\left.\mathrm{HNNMe}_{2}\right)\left(\mu-\eta^{2}-\mathrm{HOMe}_{2} \mathrm{CCCH}_{2}\right)(\mu-\mathrm{CO})_{2}(\mathrm{CO})_{6}\right]$ (4) and $\left[\mathrm{Ru}_{3}\left(\mu_{3}-\eta^{2}-\right.\right.$ $\left.\left.\mathrm{HNNMe}_{2}\right)\left(\mu_{3}-\eta^{2}-\mathrm{HCCHCMe}_{2} \mathbf{O H}\right)(\mu-\mathrm{CO})_{2}(\mathrm{CO})_{6}\right]$ (14): A solution of 1 ( $50 \mathrm{mg}, 0.081 \mathrm{mmol}$ ) and 2-methylbut-3-yn-2-ol ( $9 \mu \mathrm{~L}, 0.089 \mathrm{mmol}$ ) in THF ( 20 mL ) was stirred under reflux for 15 min . The color changed from yellow to orange. The solvent was removed under reduced pressure and the residue was separated by TLC (silica gel). Hexane/dichloromethane ( $1 / 1$ ) eluted two bands. Compound $\mathbf{4}$ was extracted from the first band and was isolated as an orange solid ( $8 \mathrm{mg}, 12 \%$ ). Compound $\mathbf{1 4}$ was extracted from the second band and was isolated as dark yellow solid ( $21 \mathrm{mg}, 39 \%$ ). A dark residue remained uneluted in the base line.
Reaction of 1 with methyl propiolate: synthesis of $\left[\mathrm{Ru}_{3}\left(\mu_{3}-\eta^{2}-\right.\right.$ $\left.\left.\mathrm{HNNMe}_{2}\right)\left(\mu-\eta^{2}-\mathrm{HCCHCO}_{2} \mathrm{Me}\right)(\mu-\mathrm{CO})_{2}(\mathrm{CO})_{6}\right] \quad$ (5), $\left[\mathrm{Ru}_{3}\left(\mu_{3}-\eta^{2}-\right.\right.$ $\left.\left.\mathrm{HNNMe}_{2}\right)\left(\mu_{3}-\eta^{2}-\mathrm{MeO}_{2} \mathrm{CCCH}_{2}\right)(\mu-\mathrm{CO})(\mathbf{C O})_{7}\right] \quad(10), \quad$ and $\left[\mathrm{Ru}_{3}\left(\mu_{3}-\eta^{2}-\right.\right.$ $\left.\mathrm{HNNMe}_{2}\right)\left(\mu_{3}-\eta^{2}-\mathrm{HCCHCO}_{2} \mathrm{Me}\right)(\boldsymbol{\mu}-\mathrm{CO})(\mathbf{C O})_{7}$ ] (11): A solution of $\mathbf{1}$ $(100 \mathrm{mg}, 0.162 \mathrm{mmol})$ and methyl propiolate ( $16 \mu \mathrm{~L}, 0.179 \mathrm{mmol}$ ) in THF $(30 \mathrm{~mL})$ was stirred under reflux for 30 min . The color changed from yellow to orange. The solvent was removed under reduced pressure, the residue was dissolved in dichloromethane ( 2 mL ), and the resulting solution was supported on a silica gel chromatographic column ( $3 \times 20 \mathrm{~cm}$ ) packed in hexane. Hexane/dichloromethane (3/2) eluted 10, which was isolated as an orange solid after solvent removal ( $47 \mathrm{mg}, 43 \%$ ). Hexane/ dichloromethane (2/3) eluted 11, which was isolated as an orange solid after solvent removal ( $18 \mathrm{mg}, 16 \%$ ). Hexane/dichloromethane (1/4) eluted 5, which was isolated as an orange solid after solvent removal ( $7 \mathrm{mg}, 6 \%$ ).
Reaction of 1 with phenylacetylene: synthesis of $\left[\operatorname{Ru}_{3}\left(\mu_{3}-\eta^{2}-\right.\right.$ $\left.\left.\mathrm{HNNMe}_{2}\right)\left(\mu_{3}-\eta^{2}-\mathrm{PhCCH}_{2}\right)(\mu-\mathrm{CO})(\mathbf{C O})_{7}\right]$ (9) and $\left[\mathrm{Ru}_{3}\left(\mu_{3}-\eta^{2}-\right.\right.$ $\left.\left.\mathrm{HNNMe}_{2}\right)\left(\mu_{3}-\boldsymbol{\eta}^{2}-\mathrm{HCCHPh}\right)(\boldsymbol{\mu}-\mathrm{CO})_{2}(\mathbf{C O})_{6}\right]$ (13): A solution of $\mathbf{1}(50 \mathrm{mg}$, $0.081 \mathrm{mmol})$ and phenylacetylene ( $10 \mu \mathrm{~L}, 0.089 \mathrm{mmol}$ ) in THF ( 20 mL )
was stirred under reflux for 20 min . The color changed from yellow to red. The solvent was removed under reduced pressure. A ${ }^{1} \mathrm{H}$ NMR spectrum of the residue indicated the presence of $\mathbf{9}$ and $\mathbf{1 3}$ in a $3 / 1$ ratio. The solid residue was recrystallized twice from dichloromethane/hexane to give $\mathbf{9}$ as an orange solid ( $32 \mathrm{mg}, 57 \%$ ). Compound $\mathbf{1 3}$ was best prepared by heating under reflux a solution of a $3 / 1$ mixture of $\mathbf{9}$ and $\mathbf{1 3}(50 \mathrm{mg}$, 0.072 mmol ) in toluene $(10 \mathrm{~mL})$ for 10 min . The solvent was removed under reduced pressure and the solid residue was recrystallized twice from dichloromethane/hexane to give the product as an orange solid ( $36 \mathrm{mg}, 65 \%$ ).
Reaction of 2 with acetylene: synthesis of $\left[R u_{3}\left(\mu_{3}-\eta^{2}-M e N N H M e\right)\left(\mu-\eta^{2}-\right.\right.$ $\left.\left.\mathrm{HCCH}_{2}\right)(\mu-\mathrm{CO})_{2}(\mathrm{CO})_{6}\right]$ (isomers 17 and 20) and $\left[\mathrm{Ru}_{3}\left(\mu_{3}-\eta^{2}-\mathrm{MeNNH}-\right.\right.$ $\left.\mathbf{M e})\left(\mu_{3}-\boldsymbol{\eta}^{2}-\mathbf{H C C H}_{2}\right)(\boldsymbol{\mu} \mathbf{- C O})(\mathbf{C O})_{7}\right]$ (22): Acetylene was gently bubbled through a solution of $2(50 \mathrm{mg}, 0.081 \mathrm{mmol})$ in THF ( 30 mL ) under reflux for 20 min . The color changed from yellow to orange. The solvent was removed under reduced pressure and the residue was separated by TLC (silica gel) with hexane/dichloromethane (2/1) as eluant. The bands were extracted to give, in order of elution, $\mathbf{1 7}$ (orange solid, 15 mg , $30 \%$ ), $\mathbf{2 0}$ (orange solid, $5 \mathrm{mg}, 10 \%$ ), and $\mathbf{2 2}$ (yellow solid, $17 \mathrm{mg}, 34 \%$ ).
Reaction of 2 with diphenylacetylene: synthesis of $\left[R u_{3}\left(\mu_{3}-\eta^{2}-M e N N H-\right.\right.$ $\left.\mathrm{Me})\left(\mu-\eta^{2}-\mathrm{PhCCHPh}\right)(\mu-\mathrm{CO})_{2}(\mathrm{CO})_{6}\right]$ (isomers 15 and 18) and $\left[\mathrm{Ru}_{3}\left(\mu_{3}-\eta^{2}-\right.\right.$ MeNNHMe) $\left.\left(\mu_{3}-\eta^{2}-\mathrm{PhCCHPh}\right)(\mu-\mathrm{CO})_{2}(\mathbf{C O})_{6}\right]$ (23): A solution of 2 ( $50 \mathrm{mg}, 0.081 \mathrm{mmol}$ ) and diphenylacetylene ( $17 \mathrm{mg}, 0.089 \mathrm{mmol}$ ) in THF ( 30 mL ) was stirred under reflux for 35 min . The color changed from yellow to dark orange. The solvent was removed under reduced pressure and the residue was separated by TLC (silica gel) with hexane/dichloromethane (5/1) as eluant. Three bands were eluted and extracted to give, in order of elution, $\mathbf{2 3}$ (yellow solid, $6 \mathrm{mg}, 10 \%$ ), $\mathbf{1 8}$ (red solid, 12 mg , $19 \%$ ), and 15 (orange solid, $14 \mathrm{mg}, 23 \%$ ).
Reaction of 2 with phenylacetylene: synthesis of $\left[R u_{3}\left(\mu_{3}-\eta^{2}-\mathbf{M e N N H}-\right.\right.$ $\left.\mathrm{Me})\left(\mu-\eta^{2}-\mathrm{PhCCH}_{2}\right)(\mu-\mathrm{CO})_{2}(\mathrm{CO})_{6}\right]$ (isomers 16 and 19) and $\left[\mathrm{Ru}_{3}\left(\mu_{3}-\eta^{2}-\right.\right.$ MeNNHMe) $\left.\left(\mu_{3}-\eta^{2}-\mathbf{P h C C H}_{2}\right)(\mu-\mathbf{C O})(\mathbf{C O})_{7}\right]$ (21): A solution of $2(50 \mathrm{mg}$,

$0.081 \mathrm{mmol})$ and phenylacetylene ( $10 \mu \mathrm{~L}, 0.089 \mathrm{mmol}$ ) in THF ( 30 mL ) was stirred under reflux for 15 min . The color changed from yellow to bright orange. The solvent was removed under reduced pressure and the residue was separated by TLC (silica gel) with hexane/dichloromethane $(5 / 1)$ as eluant. Three bands were eluted and extracted to give, in order of elution, $\mathbf{2 1}$ (yellow solid, $15 \mathrm{mg}, 27 \%$ ), $\mathbf{1 9}$ (red solid, $10 \mathrm{mg}, 18 \%$ ), and 16 (orange solid, $16 \mathrm{mg}, 29 \%$ ).
$\mathbf{X}$-ray structures of $\mathbf{3 , 5 , 1 0 , 1 1}, \mathbf{1 2}$, and 15: Diffraction data were collected on a Nonius Kappa-CCD diffractometer using graphite-monochromated $\mathrm{Cu}_{\mathrm{K} \alpha}$ radiation. Data were reduced to $F_{\mathrm{o}}^{2}$ values. Absorption corrections were applied using $\mathrm{XABS}^{[19]}$ for $\mathbf{3}, \mathbf{5}, \mathbf{1 0}, \mathbf{1 1}$, and 15, and SORTAV ${ }^{[20]}$ for 12. Structures were solved by Patterson interpretation using the program DIRDIF-96. ${ }^{[21]}$ Isotropic and full-matrix anisotropic least-squares refinements were carried out using SHELXL-97. ${ }^{[22]}$ The C1, C20, and C42 carbon atoms of $\mathbf{1 2}$ and the H atoms of all structures were refined with isotropic thermal parameters. All remaining non-H atoms were refined anisotropically. The molecular plots were made with the EUCLID program package. ${ }^{[23]}$ The WINGX program system ${ }^{[24]}$ was used throughout the structure determinations. Crystal, measurement, and refinement data for the compounds studied by X-ray diffraction are listed in Table 8.
CCDC-238358 (3), CCDC-238359 (5), CCDC-238360 (10), CCDC-238361 (11), CCDC-238362 (12), and CCDC-238363 (15) contain the supplementary crystallographic data for this paper. These data can be obtained free of charge via www.ccdc.cam.ac.uk/conts/retrieving.html (or from the Cambridge Crystallographic Data Centre, 12 Union Road, Cambridge CB21EZ, UK; fax: (+44) 1223-336-033; or deposit@ccdc.cam.uk).
Kinetic measurements: All kinetic experiments were run under pseudo-first-order conditions at a $\left[\mathrm{Ph}_{2} \mathrm{C}_{2}\right] /[\mathbf{1}]$ ratio of at least 15 . Data were obtained by measuring the disappearance of the IR absorption of $\mathbf{1}$ at $2081 \mathrm{~cm}^{-1}$. The spectra were recorded in absorbance mode on a PerkinElmer FT Paragon 1000 spectrophotometer using a Specac P/N 21525 variable-temperature cell with 0.5 mm -spaced NaCl windows. In each experiment, $\mathbf{1}(10 \mathrm{mg}, 0.016 \mathrm{mmol})$ and the appropriate amount of diphenylacetylene were dissolved in cold $\left(0^{\circ} \mathrm{C}\right)$, dry, and deoxygenated toluene (total volume 10 mL ). A portion of this solution was transferred with a syringe to the IR cell, which was previously preheated to the appropriate temperature. After an equilibration time of 2 min , the absorbance of the IR absorption at $2081 \mathrm{~cm}^{-1}$ was recorded every 2 min for 20 min . Plots of $\ln A_{t}\left(A_{t}\right.$ is the absorbance at time $\left.t\right)$ vs time were linear for all reactions ( $r^{2}>0.99$ ). The slopes of these lines yielded the observed rate constants $k_{\text {obs }}$. Plots of $k_{\text {obs }}$ vs $\left[\mathrm{Ph}_{2} \mathrm{C}_{2}\right]$ at each temperature were also linear ( $r^{2}>$ $0.95)$. Second-order rate constants $k_{2}$ were calculated from the slopes of these lines ( $k_{\mathrm{obs}}=k_{2}\left[\mathrm{Ph}_{2} \mathrm{C}_{2}\right]$ when $\left.\left[\mathrm{Ph}_{2} \mathrm{C}_{2}\right] \gtrdot[\mathbf{1}]\right)$. Activation parameters were derived from the Eyring equation.
Theoretical calculations: All the minimum-energy structures reported herein were optimized by hybrid DFT within the Gaussian 98 program suite ${ }^{[25]}$ by using Becke's three-parameter hybrid exchange-correlation functional ${ }^{[26]}$ containing the nonlocal gradient correction of Lee, Yang, and Parr (B3LYP). ${ }^{[27]}$ The Hay-Wadt Los Alamos National Laboratory two-shell double- $\zeta$ (LANL2DZ) basis set, with relativistic effective core potentials, was used for the Ru atoms. ${ }^{[28]}$ The basis set used for the remaining atoms was $6-31 \mathrm{G}$ with addition of ( $\mathrm{d}, \mathrm{p}$ ) polarization for all atoms. All optimized structures were confirmed as minima by calculation of analytical frequencies. For each calculation, the input model molecule was based on one of the X-ray structures reported in this article, conveniently modified by changing the appropriate R groups.
