Both triphenylphosphine ligands of the cluster complex $[Ru_3(\mu-H)(\mu_3-ampy)(PPh_3)_2(CO)_7]$ (ampy = 2-amino-6-methylpyridinate; la) undergo a carbon–phosphorus bond scission on reaction with hydrogen (toluene, 110 °C, 1 atm) to give the η^1 -phenyl-bridged derivative [Ru₃(μ -Ph)-(μ₃-ampy)(μ-PPh₂)₂(CO)₆] (2a). The compound 2a·CH₂Cl₂ has been characterized by X-ray crystallography. An extended Hückel molecular orbital calculation describing the interaction of the bridging phenyl group with the trimetallic fragment is also reported. The new complexes $[Ru_3(\mu-H)(\mu_3-ampy)(ER_3)_2(CO)_7](ER_3 = PMe_2Ph(1b), PCy_3(1c), P(p-tolyl)_3(1d), AsPh_3(1e))$ have been prepared in order to compare their behavior toward hydrogen with that of complex 1a; only 1d and 1e gave products analogous to 2a, whereas 1b and 1c (unlike the others, 1c is not isostructural with 1a) gave mixtures of unidentified products. Another η^1 -phenyl-bridged compound, namely, $[Ru_3(\mu-Ph)(\mu_3-mbim)(\mu-PPh_2)_2(CO)_6]$ (mbim = 2-mercaptobenzimidazolate) has been obtained, without the use of hydrogen, from the reaction of $[Ru_3(\mu-H)(\mu_3-mbim)(CO)_9]$ with PPh₃ in refluxing THF.

Introduction

We have recently published^{1,2} that the triruthenium cluster complexes $[Ru_3(\mu-H)(\mu_3-ampy)(CO)_9]^3$ (ampy = 2-amino-6-methylpyridinate) and its monosubstituted derivative $[Ru_3(\mu-H)(\mu_3-ampy)(PPh_3)(CO)_8]^4$ are efficient catalyst precursors for the homogeneous hydrogenation of diphenylacetylene under mild conditions. In this context, in a preliminary communication,5 we briefly reported that the disubstituted derivative $[Ru_3(\mu-H)(\mu_3-\mu_3)]$ ampy)(PPh₃)₂(CO)₇]⁶ (1a) (Chart 1), a poor catalyst precursor for hydrogenation reactions, reacts with hydrogen, undergoing two P-C bond cleavages which gave rise to the first example in ruthenium chemistry of a complex containing a bridging η¹-phenyl ligand: [Ru₃(μ-Ph) $(\mu_3$ -ampy) $(\mu$ -PPh₂)₂(CO)₆] (2a). We now report, together with full details of the synthesis and characterization of complex 2a, the preparation of other ruthenium cluster complexes containing bridging η^1 -aryl ligands, starting not only from derivatives of $[Ru_3(\mu-H)(\mu_3-ampy)(CO)_9]$ containing triphenylarsine or triarylphosphine ligands, i.e. $[Ru_3(\mu-H)(\mu_3-ampy)(L)_2(CO)_7]$ (L = AsPh₃, P(p-tolyl)₃), but also from trinuclear complexes containing μ_3 ligands different from ampy, i.e. $[Ru_3(\mu-H)(\mu_3-mbim)(CO)_9]$ (mbim = 2-mercaptobenzimidazolate). The results of a molecular orbital calculation (extended Hückel level) on a model compound analogous to complex 2a are also included.

Many metal-mediated P-Ph cleavage reactions are now

known.^{7,8} They usually lead to phosphido-bridged derivatives as well as to benzene,9,10 benzaldehyde,10,11 or biphenyl. 10,12 However, very few σ-phenyl-μ-diphenylphosphido derivatives have been isolated 13 although they have often been claimed as intermediates in these reactions. 11b,12 Moreover, prior to this work, the cluster compound [Os3-

 $(\mu\text{-Ph})(\mu_3\text{-PPh}_2\text{C}_6\text{H}_4)(\mu\text{-PPh}_2)(\text{CO})_8]^{14}$ was, as far as we are aware, the only known transition metal complex containing a bridging η^1 -phenyl ligand arising from a P-C bond cleavage reaction. ^{15,16}

Results and Discussion

The reaction of compound 1a with hydrogen (1 atm) in refluxing toluene (no reaction was observed in refluxing THF) gives $[Ru_3(\mu-Ph)(\mu_3-ampy)(\mu-PPh_2)_2(CO)_6]$ (2a) (Chart 2) as the major component of a mixture of products which was separated by chromatographic methods. The carbonyl region of its ¹³C{¹H} NMR spectrum contains only four resonances and its 31P{1H} NMR spectrum consists of only one singlet resonance at a high chemical shift (192.3 ppm), indicating the transformation of the terminal PPh₃ ligands of 1a into bridging PPh₂ ligands.¹⁷ The simplicity of these spectra, which suggests a symmetric structure, contrasts with the ¹H NMR spectrum, which is much more complicated in the 9.0-6.5 ppm region than that of complex la and which contains no hydride resonances. Since these spectroscopic data were insufficient to unequivocally assign the structure of complex 2a, an X-ray diffraction study was carried out (Figure 1).5

The cluster consists of an isosceles triangle of ruthenium atoms triply bridged by the ampy ligand, with the short edge (Ru(2)-Ru(3) 2.637(2) Å) spanned by the amido fragment and by one carbon atom of the phenyl group, and with the two longest edges also bridged by PPh₂ ligands. The μ,η^1 -phenyl ring is planar and essentially

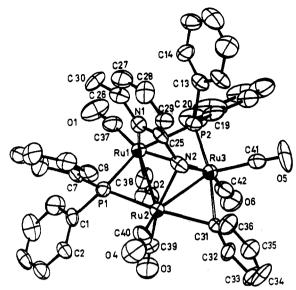

Figure 1. Molecular structure of $[Ru_3(\mu-Ph)(\mu_3-ampy)(\mu-PPh_2)_2(CO)_6]$ (2a).

orthogonal to the Ru(2)-Ru(3) vector, involving a Ru(2)-C(31)-Ru(3) bond angle of 69.0(4)°, Ru(2)-C(31)and Ru(3)-C(31) bond distances of 2.32(1) and 2.34(1) Å, respectively, and a dihedral angle between the metal triangle and the Ru(2)-C(31)-Ru(3) plane of 9.8(3)°. The ipso carbon atom of the phenyl ring (C(31)) is 0.33(1) Å away from the plane defined by the metal triangle, on the side opposite the ampy ligand. The Ru(2)-Ru(3) bond distance (2.637(2) Å) is shorter than the other Ru-Ru distances (Ru(1)-Ru(2) 2.970(2) Å; Ru(1)-Ru(3) 2.980(2)Å) and also shorter than the Os-Os distance (3.095(2) Å) of the phenyl-bridged edge of $[Os_3(\mu-Ph)(\mu_3-PPh_2C_6H_4) (\mu-PPh_2)(CO)_8$ and than the Ru-Ru distance (2.7531-(4) Å) of the edge bridged by the amido and the hydrido ligands in the related cluster complex $[Ru_3(\mu-H)(\mu_3,\eta^2-\mu_3)]$ anpy)(CO)₉] (anpy = 2 -anilinopyridinate).³ Overall, this structure resembles that proposed for the symmetric isomer of $[Ru_3(\mu-H)(\mu_3-ampy)(\mu-PPh_2)_2(CO)_6]$, 18 a compound that may be described as the result of a hypothetical substitution of a hydride for the bridging phenyl ligand of **2a**.

A three-center—two-electron bond model, similar to that proposed for [Al₂Ph₆], ¹⁹ could be used to explain the interaction of the bridging phenyl ring with the Ru(2) and Ru(3) atoms of complex 2a, but an interaction of the phenyl π -orbitals with the appropriate metal d orbitals might also contribute to the bonding, as suggested by the complexity of the aromatic region of the ¹H and ¹³C{¹H} NMR spectra, which implies that in solution there is no free rotation of the phenyl group about the C(31)–C(34) axis. Therefore, theoretical calculations were needed to determine the bonding situation.

The compound $[Ru_3(\mu-Ph)(\mu_3-ampy)(\mu-PH_2)_2(CO)_6]$ was subjected to an extended Hückel molecular orbital calculation. As can be observed in Figure 2, the HOMO essentially corresponds to a bonding interaction between a sp² orbital (s, p_x, p_z) of the phenyl fragment ipso carbon and the appropriate metal d orbitals. Interestingly, an analysis of the overlap population between the $[Ru_3(\mu_3-ampy)]$

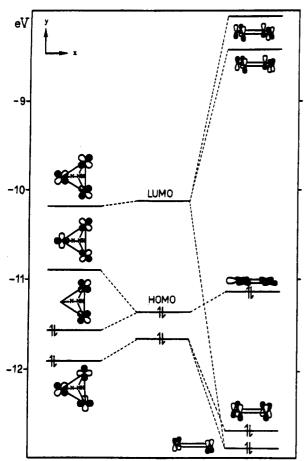

Figure 2. Interaction diagram of the fragments $[Ru_3(\mu_3-ampy)(\mu-PH_2)_2(CO)_6]^+$ and $[C_6H_5]^-$, to give $[Ru_3(\mu-Ph)(\mu_3-ampy)(\mu-PH_2)_2(CO)_6]$, in the frontier orbital region. Only the most important contributions to each MO are shown.

ampy)(μ -PH₂)₂(CO)₆]⁺ and [C₆H₅]⁻ fragments indicates that the 2p_y orbital of the phenyl fragment ipso carbon atom contributes 18% to the bonding of this fragment with the metal triangle. This contribution may be the responsible for the observed conformation of the phenyl group with respect to the metal triangle (the proximity of the equatorial CO ligands may also force the bridging phenyl group to be perpendicular to the Ru(2)-Ru(3) vector).

Although the elimination of one CO ligand and one benzene molecule from complex 1a stoichiometrically leads to 2a without the use of hydrogen, the thermolysis of 1a does not give 2a unless a hydrogen atmosphere is used; therefore, hydrido derivatives should be intermediates in this reaction. It is also interesting to note that complex 2a is remarkably stable, since it does not eliminate benzene or transform the phosphido bridges into terminal PPh₂H ligands²⁰ when exposed to hydrogen in refluxing toluene.

In order to shed light on the general significance of this reaction, i.e. for the cleavage of P–C bonds of a variety of phosphine ligands, and considering the possibility of isolating intermediates that could help us to know the reaction mechanism, the new compounds $[Ru_3(\mu-H)(\mu_3-ampy)(ER_3)_2(CO)_7]$ $(ER_3 = PMe_2Ph(1b), PCy_3(1c), P(p-tolyl)_3(1d), AsPh_3(1e))$ were prepared and their reactions with hydrogen investigated.

Treatment of $[Ru_3(\mu-H)(\mu_3-ampy)(CO)_9]$ with 2 equiv of ER₃ in refluxing THF leads to the isolation of $[Ru_3-ampy]$

 $(\mu-H)(\mu_3-ampy)(ER_3)_2(CO)_7$ (ER₃ = PMe₂Ph (1b), PCy₃ (1c), P(p-tolyl)₃ (1d), AsPh₃ (1e)). Their spectroscopic data suggest that complexes 1b, 1d, and 1e are isostructural with 1a (Chart 1), which has been characterized by X-ray diffraction methods, however, the 31P{1H} NMR spectrum of 1c shows two singlets of equal intensity, indicating the presence of two different phosphorus atoms which do not couple with each other, and the 1H NMR spectrum exhibits the hydride resonance as a triplet with a coupling constant of 7.8 Hz, indicating that the hydride is cis to both phosphine ligands,6 as expected for the structure depicted in Chart 1. Steric arguments cannot explain why the structure of 1c is different from that of 1a; therefore, it seems reasonable that the difference should be caused by the higher basicity of tricyclohexylphosphine. If this is true, the compound $[Ru_3(\mu-H)(\mu_3-ampy)(PEt_3)_2(CO)_7]$, which contains a small but basic phosphine ligand, should have the same structure as 1c; in fact, the former was characterized by NMR spectroscopy²¹ as the major component of the mixture obtained by the reaction of [Ru₃- $(\mu-H)(\mu_3$ -ampy)(CO)₉] with 2 equiv of triethylphosphine, but it could not be isolated in its pure form.

As expected, compounds 1b and 1c, which contain ligands more basic than those in 1a, react with hydrogen (1 atm) more easily (1.5 h, 20 and 70 °C respectively) than 1a. Unfortunately, they give complex mixtures of hydrido derivatives (NMR) that we were unable to separate and characterize.

The behavior of complexes 1d and 1e toward hydrogen was found to be very similar to that of complex 1a. Both react with hydrogen, at 1 atm, in refluxing toluene to give mixtures of products from which the μ - η -1-aryl derivatives [Ru₃{ μ -(p-tolyl)}(μ ₃, η -2-ampy){ μ -P(p-tolyl)₂]₂(CO)₆] (2d) and [Ru₃(μ -Ph)(μ ₃, η -2-ampy)(μ -AsPh₂)₂(CO)₆] (2e) (Chart 2) could be isolated. Their spectroscopic data (see Experimental Section) are comparable to those of 2a. Unfortunately, although other products (shown to be hydride derivatives by NMR spectroscopy) were also produced in these reactions, they could not be isolated and characterized.

In order to see whether or not these P-C bond cleavage reactions could be observed in other phosphine-substituted triruthenium clusters containing μ_3 ligands different from ampy, we attempted to make the complex $[Ru_3(\mu-H)(\mu_3-mbim)(PPh_3)_2(CO)_7]$ (mbim = 2-mercaptobenzimidazolate) (1f). However, the room temperature reaction of $[Ru_3(\mu-H)(\mu_3-mbim)(CO)_9]$ with 2 equiv of triphenylphosphine always afforded inseparable mixtures of 1f and the monosubstituted derivative $[Ru_3(\mu-H)(\mu_3-mbim)(PPh_3)-(CO)_8]$, whereas the reactions at reflux temperature (THF) gave, within a few minutes, the phenyl-bridged derivative $[Ru_3(\mu-Ph)(\mu_3-mbim)(\mu-PPh_2)_2(CO)_6]$ (2f) (Chart 2).

Remarkably, unlike the synthesis of compounds 2a, 2d, and 2e, the preparation of 2f does not require the use of hydrogen and can be achieved at a lower temperature. Since all these complexes have comparable structures, the different reaction paths followed by the ampy- and the mbim-containing systems have to be related to electronic

⁽²⁰⁾ The conversion of μ -PPh2 groups into terminal PPh2H ligands by reaction with hydrogen has been described. ^{11a}

effects caused by these ligands. Unfortunately, we still know very little about these systems to rationalize their behavior.

Experimental Section

General Data. Solvents were dried over sodium diphenyl ketyl (THF, diethyl ether, hydrocarbons) or CaH2 (dichloromethane) and distilled under nitrogen prior to use. Unless otherwise stated, the reactions were carried out under nitrogen, using conventional Schlenk techniques and were routinely monitored by solution IR spectroscopy (carbonyl stretching region). The compounds $[Ru_3(\mu-H)(\mu_3-ampy)(CO)_9]^3$ and $[Ru_3-ampy](CO)_9$ $(\mu-H)(\mu_3-ampy)(PPh_3)_2(CO)_7$ (1a) were prepared as described previously. All other reagents (reagent or analytical grade) were used as received from commercial suppliers. Infrared spectra were recorded on a Perkin-Elmer FT 1720-X spectrophotometer, using 0.1-mm CaF₂ cells. ¹H, ³¹P{¹H}, and ¹³C{¹H} NMR spectra were run at 23 °C with Bruker AC-200 and AC-300 instruments, using internal SiMe₄ (¹H, ¹³C) or external 85% H₃PO₄ (³¹P) as standards ($\delta = 0$ ppm). Microanalyses were obtained from the University of Oviedo Analytical Service.

 $[Ru_2(\mu-H)(\mu_3-ampy)(PMe_2Ph)_2(CO)_7]$ (1b). A solution of [Ru₃(µ-H)(µ₃-ampy)(CO)₉] (52.2 mg, 0.079 mmol) and PMe₂Ph (23 μ L, 0.180 mmol) in THF (10 mL) was stirred at reflux temperature for 30 min. The solvent was removed under reduced pressure and the residue washed with hexane $(3 \times 6 \text{ mL})$ to give complex 1b as a red-orange solid (40 mg, 58%). Anal.  $[Ru_3\{\mu-(p-tolyl)\}(\mu_3-ampy)\{\mu-P(p-tolyl)_2\}_2(CO)_6]$ (2d). Hydrogen was bubbled through a toluene solution (40 mL) of complex 1d (72 mg, 0.059 mmol) at reflux temperature for 1.5 h. The solution was concentrated, and the products were separated in a chromatography column $(2 \times 8 \text{ cm})$ of neutral alumina (activity IV). The first band (red), which was eluted with a mixture of hexane-dichloromethane (7:1), was worked up to give complex 2d as a red solid (10 mg, 15%). Anal. Calcd for $C_{47}H_{42}N_2O_6P_2$ -Ru₃: C, 51.51; H, 3.86; N, 2.56. Found: C, 51.72; H, 3.86; N, 2.56. IR (THF): 2023 (s), 1998 (vs), 1987 (s), 1947 (s), 1931 (s) cm⁻¹. ¹H NMR (C₆D₆): 8.3-5.4 (complex mixture of signals), 4.28 (s, NH), 2.37 (s, 6 H), 2.28 (s, 3 H), 2.06 (s, 6 H), 1.59 (s, 3 H) ppm. Selected ${}^{13}C\{{}^{1}H\}$ NMR (CD₂Cl₂): δ (CO) 206.3 (t, J = 4.0 Hz, 2 CO), 201.6 (t, J = 4.1 Hz, 1 CO), 197.5 (t, J = 7.6 Hz, 1 CO), 193.9 $(t, J = 2.3 \text{ Hz}, 2 \text{ CO}); \delta(\text{ampy}) 171.0, 159.1, 138.1, 117.6, 114.0,$ 31.0; $\delta(\mu$ -(p-tolyl)) 139.3 (t, J = 18.0 Hz, ipso carbon), 21.3 (Me); $\delta(P(p-tolyl)_2)$ 21.3 (2 Me), 21.1 (2 Me). ${}^{31}P{}^{1}H} NMR$ (C_6D_6): 185.7 (s) ppm.

 $[Ru_3(\mu-Ph)(\mu_3-ampy)(\mu-AsPh_2)_2(CO)_6]$ (2e). Hydrogen was bubbled through a toluene solution (25 mL) of complex 1e (70 mg, 0.0457 mmol) at reflux temperature for 40 min. The solution was concentrated under reduced pressure, and the products were separated by TLC (silica gel, 2:1 hexane-dichloromethane). The first two bands contained trace amounts of compounds which were not identified. The third band (red) was worked up to give 2e as a red solid (12 mg, 19%). Anal. Calcd for $C_{42}H_{32}As_2N_2O_{6}$ Ru₃: C, 45.29; H, 2.90; N, 2.51. Found: C, 45.03; H, 3.15; N, 2.39. IR (toluene): 2024 (s), 1993 (vs), 1987 (s), 1952 (s), 1935 (s) cm⁻¹. ¹H NMR (C_6D_6): 8.4-6.8 (complex mixture of signals), 6.70 (t, J = 7.8 Hz, 1 H, 6.55 (d, 1 H), 5.40 (d, 1 H), 4.20 (s, NH), 1.58(s, 3 H). Selected 13 C{ 1 H} NMR (CD₂Cl₂): δ (CO) 204.5 (2 CO), 199.7 (1 CO), 195.9 (1 CO), 192.9 (2 CO); δ (ampy) 170.5, 158.1, 137.4, 116.9, 112.6, 30.2 ppm.

[Ru₃(μ -H)(μ ₃-mbim)(CO)₉]. This complex was prepared by following the anionic route described by Lavigne and co-workers23 for the synthesis of $[Ru_3(\mu-H)(\mu_3-pyS)(CO)_9]$ (pyS = pyridine-2-thiolate): K-selectride (312 µL, 1 M in THF, 0.312 mmol) was added to a solution of 2-mercaptobenzimidazole (52 mg, 0.34 mmol) to give a white precipitate of Kmbim. After stirring for 30 min, a solution of [Ru₃(CO)₁₂] (200 mg, 0.313 mmol) in THF (25 mL) was added. The mixture was stirred for 2.5 h and then evaporated to dryness. Dichloromethane (25 mL) and trifluoroacetic acid (27 µL) were added to the residue to give a red-orange solution and a white precipitate (KO₂CCF₃). The filtered solution was evaporated to dryness and the residue washed with hexane $(2 \times 5 \text{ mL})$ to give $[\text{Ru}_3(\mu\text{-H})(\mu_3\text{-mbim})(\text{CO})_9]$ as an orange solid (143 mg, 65%). Anal. Calcd for C₁₆H₆N₂O₉Ru₃S: C, 27.24; H, 0.86; N, 3.97. Found: C, 27.36; H, 1.02; N, 3.78. IR (THF): 2083 (m), 2051 (s), 2031 (vs), 2001 (s), 1995 (sh), 1964 (w) cm⁻¹. ¹H NMR (CD₂Cl₂): 9.88 (br s, NH), 7.5-7.3 (m, 4 H), -13.14 (s, μ -H) ppm.

 $[Ru_3(\mu-Ph)(\mu_3-mbim)(\mu-PPh_2)_2(CO)_6]$ (2f). A THF solution (15 mL) of $[Ru_3(\mu-H)(\mu_3-mbim)(CO)_9]$ (30 mg, 0.043 mmol) and PPh₃ (23 mg, 0.088 mmol) was stirred at reflux temperature for 45 min. The solvent was removed under reduced pressure and the residue introduced in a chromatography column $(10 \times 2 \text{ cm})$ of neutral alumina (activity IV). The first band (red), which was eluted with a mixture of hexane-dichloromethane (1:1), was worked up to give complex 2f as a red solid (38 mg, 83%). Anal. Calcd for C₄₃H₈₀N₂O₆P₂Ru₈S: C, 48.36; H, 2.83; N, 2.62. Found: C, 48.23; H, 3.00; N, 2.48. IR (CH₂Cl₂): 2031 (s), 2004 (vs), 1997 (s), 1958 (m), 1939 (m) cm⁻¹. ¹H NMR (acetone- d_6): 8.4-6.4 (complex mixture of signals) ppm. $^{31}P\{^{1}H\}$ NMR (acetone- d_{6}): 195.4 (s) ppm.

Molecular Orbital Calculations. Calculations were carried out at the extended Hückel level,24 on the compound [Ru₃(µ-Ph)(μ_3 -ampy)(μ -PH₂)₂(CO)₆], using the weighted H_{ii} formula.²⁵ Standard atomic parameters were taken for H, C, N, O,24 and P.26 The exponents (5) and the valence shell ionization potentials $(H_{ii}, \text{ in eV})$ for Ru were respectively 2.078 and -8.60 for 5s, 2.043 and -5.10 for 5p; a linear combination of two Slater-type orbitals $(\zeta_1 = 5.378, c_1 = 0.5340; \zeta_2 = 2.303, c_2 = 0.6365)$ was used to represent the atomic d orbitals; the H_{ii} value for 4d was set equal to -12.20 eV. The X-ray determined atomic coordinates of compound 2a were used in the calculations, except that hydrogen atoms were substituted for the phenyl groups of the phosphido

Crystal Structure of [Ru₂(μ-Ph)(μ₃-ampy)(μ-PPh₂)₂-(CO)₆]·CH₂Cl₂ (2a·CH₂Cl₂). A red crystal of 2a·CH₂Cl₂, obtained by layering pentane on a solution of the complex in dichloromethane, was used for the X-ray diffraction study. The cell dimensions were determined by least-squares refinement from the setting angles of 25 centered reflections in the range 10 $< 2\theta < 20^{\circ}$. The intensities were collected using the θ -2 θ scan method. The measurement of three standard reflections every 60 min revealed no intensity fluctuations. One set of reflections was collected up to $2\theta = 50^{\circ}$. The intensities were corrected for Lorentz and polarization effects.

The structure was solved by direct methods²⁷ and successive Fourier difference syntheses and was refined by weighted anisotropic full-matrix least-squares methods. After refinement of positional and anisotropic thermal parameters for the nonhydrogen atoms, the positions of the hydrogen atoms were calculated (C-H = 0.95 Å, B_{iso} = 4 Å²) and included as a fixed contribution to F_c . A CH₂Cl₂ molecule of solvation was refined isotropically. Scattering factors and corrections for anomalous dispersion were taken from ref 28. The drawing was made with ORTEP.29 All calculations were performed on a MicroVAX 3100 computer using the SDP program package.30 Tables of crystal and refinement data can be found as supplementary material in the preliminary communication of this work.5

Acknowledgment. This work was supported by the CICYT (Spain; Project MAT90-0173). We thank Dr. L. Ouahab (CNRS, Rennes, France) for the X-ray diffraction data. Fellowships from the Instituto de Cooperación Iberoamericana (to R.J.F.) and from the FICYT-Asturias (to A.L.) are also acknowledged.

Supplementary Material Available: Tables of bond distances and angles, anisotropic thermal parameters, positional parameters, and angles between least-squares planes (7 pages). Ordering information is given on any current masthead page.
